COPYRIGHT ACKNOWLEDGMENTS FOR ILLUSTRATIONS

Where more than one illustration is shown on a page, credits are cited from left top to bottom followed by right top to bottom. Numerals in parentheses following the credit indicate the number of illustrations from the same source which appear consecutively in the sequence noted above. The editors are indebted to Life magazine for permission to reproduce a number of the photographs appearing in these volumes. For a subject guide to illustrations, see the index in vol. 4.

INTRODUCTION

TEN EVENTFUL YEARS is the record of world events of the years 1937 through 1946. It is a report, in large part, by men and women who were active in shaping these events. It is history during that period written by those who made history.

TEN EVENTFUL YEARS is the work of more than 800 men and women from forty-five countries of the world. They have collaborated in the production of these volumes—harmoniously and with mutual respect. This should be some faint indication that peaceful collaboration between different nationalities is possible in more important matters.

These volumes do not constitute a completely objective encyclopaedia of the times. The volumes are the times. Contributions to them by eminent scientists, politicians, lawyers, generals, statesmen, and men and women of many different interests are often expressions of opinion. It was believed by the editors and publishers of these books that they might very well be so, for out of such varying points of view—often disputed—was fashioned the character and significance of the decade.

No decade, perhaps, in the march of man is so rich in startling changes in physical and spiritual aspects of living heretofore commonly accepted as more or less permanent. Words and their meanings from the mouths and pens of often selfish, cynical and power-drunk men became weapons of unexpected malignancy. The decade witnessed active war, but also peace, which was no peace. It witnessed, too, great scientific achievements, great sacrifices, courage and faith. Although astronomical expenditures were made for war, more money and effort than ever before were expended to help the starving and the homeless of the world.

In the four volumes are revealed the last ten years of nineteen hundred and forty-six years of the Christian era. One can see in this particular decade the pattern of all the other years which have gone before; and man's extraordinary progress seems to be only by the light of fallen cities. If his advances can be made only through turmoil and pain, the decade must hold hope for and promise of a better way of life throughout the world.

WALTER YUST

EDITORS AND CONTRIBUTORS

WALTER YUST, Editor of Encyclopædia Britannica and of 10 Eventful Years JOHN V. DODGE, Associate Editor of 10 Eventful Years

(Initials and names of contributors to 10 Eventful Years with the principal articles written by them. The arrangement is alphabetical by initials.)

Abbreviations

Had Rip Van Winkle returned to the U.S. scene during the years 1937–46, he would have needed at his elbow a key to current abbreviations in reading reports of government activities in his daily newspaper. Without such a key, he would have been unable either to identify the players or follow the score. For the use of abbreviations to denote government and other organizations greatly increased during the decade, a period which saw an enormous expansion in the apparatus of government.

Because of the limited space available to them, headline writers faced a difficult problem in dealing with the many new agencies created by the Roosevelt administration to carry out the New Deal program. The problem was conveniently solved by the employment of alphabetical abbreviations, both in the headlines and in the text of news dispatches. Possessing the cardinal virtue of brevity, many of these verbal shortcuts became part of the everyday speech of the period.

The use of abbreviations, of course, was by no means new. The letters G.O.P. and G.A.R., for example, had been familiar to newspaper readers for many years. Equally familiar were the letters FBI, long used for the Federal Bureau of Investigation. To these and other old timers were

Eventful Years

added a legion of other abbreviations. The list, indeed, had become so long that a study of these abbreviations necessarily held high priority on the agenda of new residents in the national capital.

Some of the abbreviations used for the new agencies, such as OPA, OSS, and U.S.O., came trippingly to the tongue. Others, composed of a less euphonious combination of letters, such as ODHWS, though convenient enough for the headline writer, had little appeal either to the eye or the ear. Fortunate, therefore, the agency born with a name whose alphabetical abbreviation had the swing and catch of a slogan!

Though four-, five- or even six-letter combinations were represented on the list, three-letter words comprised the bulk of the abbreviations for federal agencies used during the decade. NIRA—National Industrial Recovery administration—soon became NRA, far more effective as a recovery slogan than its four letter predecessor.

In several instances the same symbols were used for two separate agencies, for example, CCC—Civilian Conservation corps and Commodity Credit corporation. Occasionally, too, letters were appropriated for a federal unit previously employed as an abbreviation for a private or-

ganization or association. In short, there were few if any ground rules in the game of abbreviation making.

A.W.O.L., K.P., and other abbreviations continued to hold a place of respectable antiquity in the army's vocabulary. World War I made the public familiar with many abbreviations, among them A.E.F., S.O.S. (services of supply) and G.H.Q. World War II, which lasted longer and required an even more complete mobilization of manpower and resources, gave a correspondingly wider field for verbal shortcuts. It was this war that saw popular acceptance of G.I., government issue, as the abbreviation for the U.S. soldier, counterpart of the older British Tommy Atkins, the French poilu and the U.S. doughboy of 1917-18.

Students of World War II manuals found it necessary to acquaint themselves with hundreds of abbreviations officially authorized for technical military terms. To the layman, most of these were of little importance. Some military abbreviations, however, such as AAF, E.T.O., USFET and S.H.A.E.F. made almost daily appearances in the press.1

The army and navy both used abbreviations for their top commands. General Dwight D. Eisenhower was officially known as S.C.A.E.F.—supreme commander Allied expeditionary force.

The corresponding designation for General Douglas A. MacArthur was S.C.A.P.-supreme commander for the Allied powers.

In the navy, COMINCH denoted commander in chief, U.S. fleet, while CINCPAC and CINCLANT represented respectively the commanders in chief of the Pacific and

Among the women's services, abbreviations were widely used. In this group were the WAC, WAVES, WAFS and WASP. The American Women's Voluntary services, an organization of civilian women war workers, was better known by its abbreviation AWVS.

With increased power and improved status, organized labour played a big part in the history of the decade. As seen from the press headlines, abbreviations provided the key to the labour battles of these years. As new labour organizations achieved the spotlight, the alphabet was drafted to provide the appropriate letter symbol.

Since they contributed to the news of the decade, the headline writer also used abbreviations for many national business, professional and educational associations. Here, too, as in the government and labour fields, the advantages of brevity and the economy of words apparently tipped the scales against the disadvantages of occasional confusion and the uncertainty, among some readers, as to the exact organization which a particular group of letters represented.

With public interest increasingly turned to the work of international organizations, the close of the decade brought the alphabet under a new requisition. The letters U.N.O. hit the headlines soon after the formation of the United Nations organization (the "O" and the "organization" subsequently were dropped officially), and the letters U.N.E.S.C.O., denoting the United Nations Educational, Scientific and Cultural organization, became equally familiar to newspaper readers. When news of the operations of the United Nations Relief and Rehabilitation administration came over the wires, the letters U.N.R.R.A. saved many a headache on news desks.

Like the snows of yesteryear, abbreviations once used for agencies later abolished were almost forgotten, except for former employees or historians delving into the archives of the past. Creation of new agencies, and the catapulting of other organizations into the limelight, however, more than compensated for the retirement of NRA, WPB and others.

Despite the drafts already made upon it, however, the alphabet, with its 26 letters, showed no apparent signs of exhaustion, and stood ready to provide newcomers with their appropriate and individual, if not copyrighted, symbols. As the decade ended, there were no indications in Washington that 1946 was destined to mark the end of the era of abbreviations.

Among the abbreviations commonly used during the decade for government agencies and other organizations were the following:

AAA Agricultural Adjustment administration

AAF Army air forces
A.B.C. Audit Bureau of Circulations

ABSIE American Broadcasting Station in Europe

A.C.W.A. Amalgamated Clothing Workers of America A.D.A. Alley Dwelling authority

AFCC Air force combat command AFFC Air force ferrying command

A.F.G.E. American Federation of Government Employees

A.F.L. or A. F. of L. American Federation of Labor

A.F.M. American Federation of Musicians

A.F.R.A. American Federation of Radio Artists

AGF Army Ground Forces

A.I.B. American Institute of Banking A.I.F. Australian imperial force

A.L. American legion A.L.P. American Labor party

A.M.G. Allied military government A.M.G.O.T. Allied Military Government of Occupied Territory

AMVETS American Veterans of World War II

ANC Army nurse corps

A.N.G. American Newspaper guild

ANMB Army and Navy Munitions board

A.N.P.A. American Newspaper Publishers association ANZAC Australian and New Zealand Army corps

A.P. Associated Press

ARC American Red Cross

ASCAP American Society of Composers, Authors and Publishers

A.S.N.E. American Society of Newspaper Editors

A.S.P.C.A. American Sociéty for the Prevention of Cruelty to

ASTP Army Special Training program

ATC Air transport command (army) A.T.S. Auxiliary Territorial Service (A.U.S. Army of the United States (British)

AVC American Veterans' committee

AWVS American Women's Voluntary Services

B.B.C. British Broadcasting corporation B.E.F. British expeditionary force

B.E.S. Bureau of Employment Security BEW Board of Economic Warfare

BFDC Bureau of Foreign and Domestic Commerce

B.L.E. Brotherhood of Locomotive Engineers

B.L.S. Bureau of Labour Statistics

B.O.A.E. Bureau of Agricultural Economics B.R.T. Brotherhood of Railroad Trainmen

B.W.C. Board of War Communications

CAA Civil Aeronautics administration

CAB Civil Aeronautics board

C.A.P. Civil Air patrol

C.A.R.E. Cooperative for American Remittances to Europe CCC Civilian Conservation Corps; Commodity Credit Corp.

CEA Commodity Exchange administration

C.E.D. Committee for Economic Development

C.E.F. Canadian Expeditionary Force

C.I.O. Congress of Industrial organizations

COGSIS Committee of Government Statistics and Information service

Com Z Communications Zone (military)

CPA Civilian Production administration CSB Central Statistical board

CWA Civil Works administration

CWAC Canadian Women's Army corps

¹No universally accepted rule as to the use of periods in abbreviations was followed. One common method, and the one used in these volumes, was to use periods after the initials of all organizations except U.S. government agencies and some, but not all, organizations whose letters formed pronounceable words such as WAVES, etc. Newspapers and periodicals generally omitted periods in all cases, with space limitations, no doubt, in mind.—Ed.

Abdullah, Ibn Hussein

King Abdullah of Trans-Jordan (1882—), was born in Mecca, second son of the Sherif Hussein of Mecca (who became King Hussein of the Hejaz) and brother of King Feisal II. In 1921, when Winston Churchill, then colonial minister, set up at the Cairo conference the states of Iraq, Saudi Arabia and Trans-Jordan, Abdullah was made emir of Trans-Jordan, carved out of the hinterland of Palestine and Syria. After assuming the emirate, Abdullah concluded a treaty with Britain (1928) and established a constitution. Trans-Jordan's Arab Legion relieved British troops of frontier duties in Palestine during World War II and fought as part of the British expeditionary force during the Iraqi revolt (1941).

Toward the close of World War II, Abdullah announced his opposition to continuation of the mandate system, declaring it destroyed the sense of unity the Arabs had when they were "one people." He added that creation of a Jewish homeland in Palestine caused Arab "disunity."

On March 22, 1946, Britain ended its mandate over Trans-Jordan, giving that state full independence, and signed a treaty with that country which conferred on Britain the right to maintain garrisons on Trans-Jordan's soil. The treaty, however, was not signed by the respective governments but by King George and the emir, who was personally obligated to provide lines of communication through his country. On May 25, 1946, Abdullah exchanged his emirate for a kingdom and was formally proclaimed king of Trans-Jordan in impressive ceremonies at his capital.

Reports from Amman late in 1946 said Abdullah hoped to make Trans-Jordan the nucleus of a "Greater Syria," to include parts of Iraq, Syria and Palestine. This would make Abdullah ruler of a vast Arab territory and place him on equal terms with Ibn Sa'ud of Saudi Arabia and Farouk of Egypt.

Abe, Nobuyuki

Abe (1875-), Japanese army officer and statesman,

was born in Nov. 1875 at Ishikawa. A graduate of the Japanese Military Officer's school (1897), he held a number of high military posts. In his rise in the army hierarchy, he became successively vice-minister for the army, acting minister of the army and, in 1932, commander of the Taiwan (Formosa) army. Abe assumed the premiership at a moment of political confusion in Japan caused by the nazi-soviet pact. In Aug. 1939, while Baron Kiichiro Hiranuma was premier, this event, the consequences of which were inaccurately assessed by Japanese politicians, gave rise to great alarm in Tokyo. It was felt that Adolf Hitler had "double-crossed" his Japanese allies by conclusion of the pact with Joseph Stalin. As a result, Hiranuma resigned five days after the pact was signed and Abe became premier. Abe's tenure was undistinguished by any notable acts of statesmanship, although the first action of his cabinet was a statement that Japan did not intend to "become involved in the European war." He resigned Jan. 14, 1940, and was succeeded as prime minister by Admiral Mitsumasa Yonai. Abe, who was appointed governorgeneral of Korea in 1944, was ousted from that office in Sept. 1945 by Lt. Gen. John R. Hodge of the U.S. occupation forces. Later that month, Gen. Douglas MacArthur ordered Abe's arrest.

Aberhart, William

Aberhart (1878–1943), Canadian politician, was born on Dec. 30, 1878, near Kippen, Ont. Educated at Hamilton Normal school and Queen's university, he settled in Calgary, where he organized a Bible class that later expanded into the Calgary Prophetic institute. He became widely known for his religious broadcasts on behalf of the institute. In 1935, he became premier of Alberta as head of the Social Credit party, which promised monthly dividends of \$25 for every citizen; in the elections that year his party won 56 of the 63 seats in the Alberta legislature. Aberhart's program was based on the theories of social credit propounded in London by Major C. H. Douglas. Later, provincial and dominion courts and the privy council ruled his legislation unconstitutional, and in 1938 he set up a modified form of social credit. Aberhart, who was re-elected in 1940, died in Vancouver, B.C., May 23, 1943.

Abrasives

The salient data on the production of abrasives in the United States during years 1937-45 inclusive are presented in Table I.

In general, the need for abrasives was considerably aug-

Table I.—United States Production of Abrasives (In short tons, or as indicated) 1937 1938 1939 1940 1941 1942 1943 1944 1945 Aluminous Abrasives 2,029 765 2,131 2,989 5,765 4.876 1,046 Carbon Abrasives Industrial diamonds,* carats 1,885,970 1,397,398 3,570,111 3,809,856 6,882,248 11,207,003 12,175,430 12,656,835 10,793,285 Si ica Abrasives 18,611 502,328 237,167 22,188 13,012 31,855 856,309 342,218 30,212 34,959 668,027 310,512 41,685 1,001,814 487,665 29,301 99,445 837,662 541,350 82,379 897,983 558,606 65,878 806,878 1,067,178 328,156 Sand and sandstone (ground) 527,886 17,536 533,656 34,936 33,474 14,912 Si'ica Stone Abrasives 4,653 \$3,743 1,553 7,917 \$11,084 2,517 8,790 \$6,558 4,533 13,573 \$15,579 1,963 3,411 13,561 12,763 \$10,391 1,918 2,576 10,732 \$9,240 1,891 2,585 10,033 \$8,305 2,924 2.063 1.982 15,487 9,924 Silicate Abrasives 4,716 82,407 5,501 117,310 4,357 126,522 6,306 157,001 88,757 Artificial Abrasives Silicon carbide † . . . mented during World War II, with cases of output doubled and redoubled. However, in a few cases, the product was not particularly involved in war production, and with civilian supplies generally suppressed in favour of those needed for the war program, the product in question showed little or no increase, or even a decrease in output. For example, the output of garnet during the war years averaged little above that for 1937, most of the amount needed for the war program being supplied by decreasing ordinary industrial uses. The output of tripoli dropped more than half; the increase in abrasive uses was more than offset by decreases in other types of uses.

The most outstanding increase in demand for abrasives for the war program was that of industrial diamonds. Imports into the United States had been increasing heavily after 1929, as industry developed new uses, but where prewar increases had been measured in thousands of carats, war increases were in the millions. For a more detailed discussion, see Diamonds.

The United States was not able to supply its full demand for abrasives from domestic sources, and had to rely on imports for a portion of the total. Domestic supply was completely lacking only for industrial diamonds and corundum, and these two comprised the major portion of the imports. The imports of other types of abrasives were relatively small as compared with the domestic output. A comparison of domestic output, total imports and imports other than industrial diamonds or corundum is shown in Table II.

Table II.—Comparison of U.S. Output and Imports and Exports of Abrasives
(Thousands of dollars)

		Output		impor	rts		Exports		
			Total	Diamonds	Corundum	Others			
1937		\$12,259	\$7,418	\$6,542	\$135	\$741	\$1,160		
1938		8.959	4.727	4,213	139	375	1.075		
1939		10,318	10,247	9,727	105	415	1,416		
1940		13.995	11.51 <i>7</i>	11,02 <i>7</i>	165	325	1,606		
1941		22,089	15,470	14,909	287	274	3,220		
1942		30.018	22.602	21,785	261	556	6,684		
1943		35,830	22,565	21,738	332	495	3,511		
1944		34,403	23.534	22,658	437	439	2,092		
1945		31,695	13,493	12,757	457	279	2,088		

On the average, total imports ran about two-thirds of production, but most of the total consisted of the two products entirely imported—industrial diamonds and corundum—and after deducting these, the imports competing with domestic output were relatively small.

Exports of abrasive materials from the United States remained largely confined to manufactured materials, a large percentage of the value of which was manufacturing cost, so that the exports listed in Table II represented only a small portion of the raw materials value in the output column.

Accident and Health Insurance

See Insurance.

Accidents

Accidental deaths in the United States for the ten years from 1937 through the first eight months of 1946 totalled 943,090. Of these, 305,242 were motor vehicle deaths (see below); 157,500 were classified as public (as distinguished from motor vehicle deaths); 308,500 accidental deaths occurred in homes; 165,200 were occupational deaths and 41,200 were accidental deaths sustained in the United States by military personnel.

Peak year of accidental deaths during the ten-year period was 1937, when there were 106,000 fatalities. This total had been exceeded only once before; in 1936 accidental deaths reached a record of 110,052. Variation of other years were as follows:

193893,8	805
193992,6	i23
194096,8	885
1941101,5	113
194295,8	889
194399,0	13 8
1944	37
194596,0	000
1946	oo (First eight months)

There were two main trends of accidental deaths during the ten years: upward for motor vehicle fatalities; downward for all other types. In 1906, the first year for which information was available, there were only about 400 motor vehicle deaths—or a death rate of less than 1 per 100,000 population. Nonmotor vehicle deaths numbered about 79,600, a rate of 93. With a tremendous increase in travel, motor vehicle deaths rose, reaching a death rate of 30 in 1941. In that year the rate for nonmotor vehicle deaths was 46—half the 1906 rate.

In 1945, there were approximately 10,250,000 nonfatal disabling accidental injuries, in addition to the 96,000 deaths. All of these cases resulted in loss of time from usual activities beyond the day of the injury. "First-aid" injuries were not included.

For that year, wage loss, medical expense and overhead costs of insurance amounted to \$2,700,000,000. Property damage in motor vehicle accidents and fires cost \$1,100,000,000. So called "indirect" costs of occupational accidents amounted to \$1,300,000,000. These costs totalled \$5,100,000,000.

In 1937, occupational deaths reached 19,000. The following year they dropped to 16,000, went down to 15,500 in 1939, then advanced to 17,000 in 1940, to 18,000 in 1941 and to 18,500 in 1943. There was another drop in 1944 to 16,000, and that total was reached again in 1945. The trend for the first eight months of 1946 was slightly up.

In view of the rapid and enormous industrial expansion during the years 1937 through 1946, the fact that the occupational death rate did not soar to higher totals must be attributed to the intensified accident prevention work of all who had a part in the increasing production. There was a tremendous influx into industry of new workers: women, young people who had never worked before, office workers and older workers who had been out of industry for varying lengths of time.

During the war period, great emphasis was placed on integrating safety into training programs. Courses in industrial safety were sponsored by the federal government and worked out in conjunction with schools, the National Safety council and other organizations. These courses were held in every major city of the United States and were attended by thousands of men and women. Usually lim-

ited to 96 class hours, graduates took their training into various industrial jobs. Many of them became full time safety workers; others, who held production jobs, incorporated the safe practices they had learned into their regular jobs.

There was great emphasis on safety in ordnance plants, shipyards and aircraft manufacturing plants. Many of these war industries-usually considered highly hazardoushad enviable safety records.

The National Safety congress, held annually under the sponsorship of the National Safety council, continued to provide an opportunity for exchange of information in all fields of safety. Cancelled in 1945 because of travel restrictions, the congress was held in Chicago in 1946, and again attracted some 10,000 safety leaders from all parts of the United States and from numerous foreign countries.

Realizing that when peacetime activities were resumed, the United States would be confronted with the greatest accident problem in its history, safety leaders began well before the end of the war to prepare for postwar years. Spearheading the postwar highway safety program, Pres. Harry S. Truman called a Highway Safety conference in May 1946 to seek ways of mobilizing every available source of educational, engineering and enforcement skill to combat the traffic accident problem. At this conference, which was attended by some 2,000 safety leaders from state, county and city governments, federal departments and national organizations, a comprehensive program was approved. The program developed served as a guide for highway safety programs of officials and supporting nonofficial organizations throughout the United States.

There was a widening of interest in the National Traffic Safety contests sponsored by the National Safety council. These contests provided annual awards for states and cities having the best scores, taking account both of low acci-

†Approximations for these types of accidental deaths cannot be made for these

dent rates and meritorious safety activities. Iowa won the

state division of the contest in 1945; the city winner was Wichita, Kan. The decade from 1937 through 1946 saw a great expan-

sion in school, home and farm safety. Newspapers, magazines, radio and motion pictures gave a great deal of attention to safety. Hundreds of service and civic organizations began to take an active part in the safety movement for the first time. Many new state and local safety organizations came into being and many of those already established strengthened their programs. (See also Death Sta-TISTICS; INDUSTRIAL HEALTH.)

U.S. Traffic Accidents.—During the decade 1937-46, nearly 320,000 people of the United States were killed in traffic accidents, and some 11,000,000 others were injured. Resulting economic losses, including property damage, wage loss, medical expense and overhead cost of insurance, totalled approximately \$15,000,000,000.

The fact that in the face of this grim record there were many important gains in highway safety merely bespoke the magnitude of the accident prevention problem in the most highly motorized nation on earth. For the accident curve normally had tended to follow closely the travel mileage curve. Thus, the peak mileage year of 1941, when travel aggregated 333,000,000,000 mi., was also the blackest year in number of fatalities, setting an all-time high of nearly 40,000 traffic deaths.

Motor vehicle travel in the United States multiplied six times within two decades. In 1946, with some 5,000,000 fewer vehicles on the road than the 34,000,000 operating in 1941, the vast mileage of that top prewar year was being more than equalled.

In 1937, the motor vehicle fatality rate was 14.7 deaths per 100,000,000 miles. It dropped to 12 in 1938, and remained fairly stable between that figure and 11.4 through 1941. With the sharp curtailment of motor travel in the first war year of 1942, the rate declined to 10.6, and then averaged 11.3 for the next three years.

An unprecedented decrease in the fatality rate occurred in 1946, attributable to a nation-wide intensification of safety activities, notably the President's Highway Safety conference. The conference "Action Program" provided a master plan, based on sound educational, enforcement and engineering techniques, by which states and communities could achieve maximum safety and efficiency in highway transportation. In addition, the event had the effect of making people safety-conscious on a truly national scale. From 11.4 in January the rate fell to 7.8 in August, the lowest point in history.

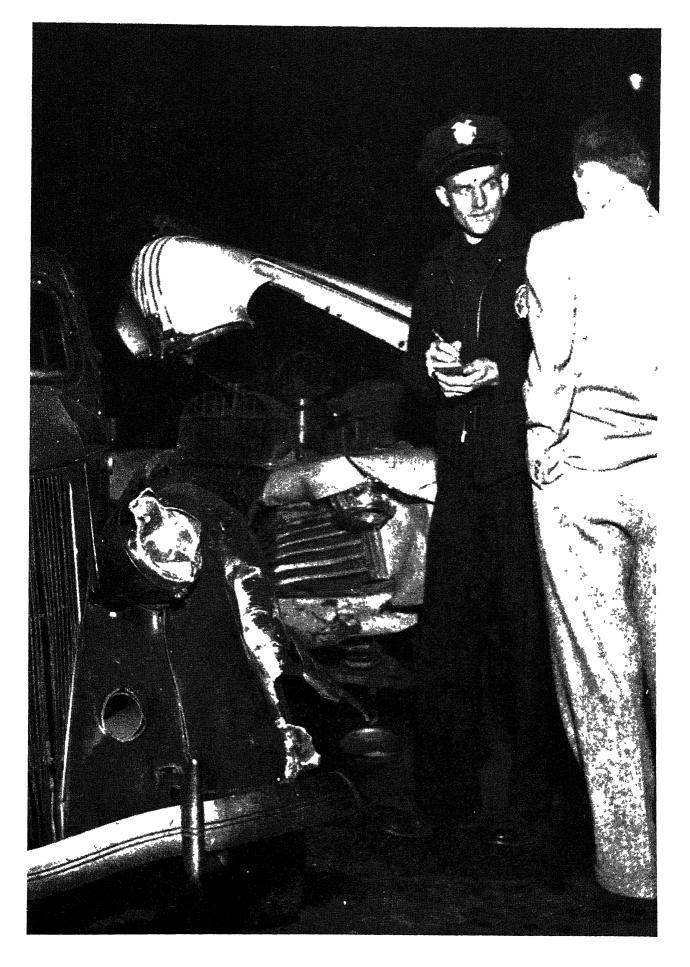

Both pedestrian and nonpedestrian deaths during the ten-year period decreased more in the larger cities than in ıural areas. Rural prewar deaths were on the rise for both pedestrian and nonpedestrian, whereas both urban trends were downward. While all wartime death tolls declined, pedestrian and nonpedestrian deaths from 1941 to 1945 fell much more rapidly in rural areas and cities under 10,000 population than in larger cities.

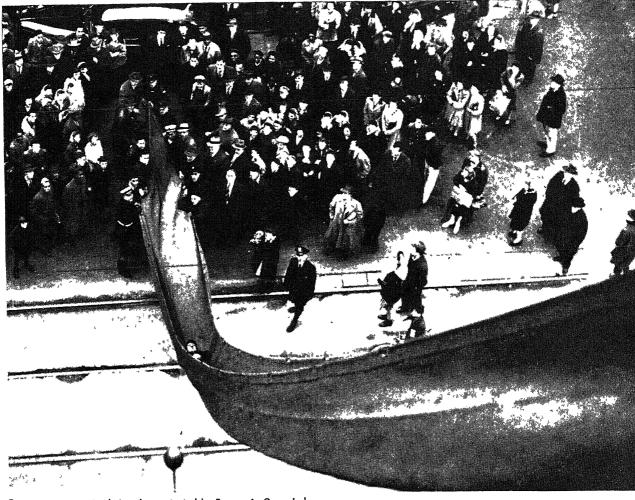

Trends at the end of the decade indicated that accident experience was reverting to the pattern which prevailed prior to World War II. Two-thirds of all traffic deaths were occurring in rural areas. Because of increased rural traffic and more effective urban accident-control measures, rural deaths increased sharply in proportion, while urban deaths showed little fluctuation.

Typical U.S. traffic accident at Los Angeles, Calif., includes the usual grotesque wreckage, gasoline leakage, traffic officer and appalled driver. Motor vehicles accounted for almost 33% of all accidental deaths during the decade 1937-46

years.

These estimates are for civilians only. The figures for earlier years include the non-motor vehicle deaths of military personnel, but there were so few such deaths that comparability is not affected.

Emergency evacuator being demonstrated by firemen in Gary, Ind. A seven-floor escape in the canvas chute averaged four seconds, as compared with two minutes by ladder

Even a brief inventory of 1937–46 safety activities disclosed substantial progress in the three basic fields of enforcement, education and engineering. Voluntary uniformity among the states in the regulation of traffic gained ground. The Uniform Vehicle code and the Model Traffic ordinances, periodically revised to keep them keyed to increasing traffic densities and design changes in both vehicles and highways, were accepted by officials and the public as recognized standards. Similarly, cities were making greater strides toward uniformity in signals, signs and road markers.

There was a widespread realization of the need for driver control through licensing, including examination, re-examination, suspension and revocation. The American Association of Motor Vehicle Administrators continued to conduct schools in various states to provide trained examiners. Only three states in the entire nation lacked an operator's licence law at the end of 1946.

As a pioneering step in selective enforcement, the International Association of Chiefs of Police in 1936 initiated a program for installing accident-prevention bureaus in city and state police departments. Their value was quickly demonstrated, when 16 cities in which bureaus were set up showed an 11.5 reduction in death rate during the first nine months of 1937, compared with the same period of 1936. This excellent program was later extended to many of the principal cities of the United States, as well as to

states. In 1946, the organization's Traffic Division made an intensive study of traffic law enforcement legislation and administrative needs for the Interim Committee on Governmental Reorganization of the California legislature. Thirty cities and six states had received traffic division service, all achieving substantial reductions in traffic fatality rates since reorganization of their traffic control programs with traffic division assistance.

The Northwestern University Traffic institute, a national centre for police training, had given basic and advanced courses in traffic control to more than 1,400 state and urban officers by the end of 1946. The institute had also established numerous regional and state training courses.

To the National Safety council belonged major credit for focusing public attention on the importance of collection and use of traffic accident records in selective enforcement. Forty-five states had enacted legislation requiring drivers to report to authorities in the event of accidents.

A national program for the improvement of traffic courts was conducted jointly by the American Bar association and the National Safety council. This needed reform was begun following publication of the noted Warren report, based on the country-wide survey of traffic laws and courts, which was sponsored in 1938 by the National Committee on Traffic Law Enforcement and the National Conference of Judicial Councils.

Traffic engineering came rapidly to the fore in the safety picture with public recognition of its vital role not only in the design and maintenance of roadways but in the scientific control of the vehicles on them. The Yale Bureau

of Highway Traffic gave specialized training in traffic engineering to graduate engineers, who then qualified for key positions with city and state highway departments.

Appreciable advances were made in all segments of safety education. Effective work was done by the National Safety council in safety organization; by the American Automobile association in driver training and pedestrian protection; by the National Congress of Parents and Teachers, the General Federation of Women's Clubs, American Legion and the National Grange in adult education; by the National Education association, Highway Education board, the Grange and the Parent-Teacher groups in child education.

One of the brighter spots in traffic safety was the accomplishment of the school patrols in the elementary schools. A third of a million youngsters were members at the end of 1946. Driver training had been instituted in more than 7,000 of the nation's 25,000 high schools in the United States.

The annual National Traffic Safety contest, sponsored by the National Safety council and the National Pedestrian Protection contest of the Automobile association, continued to be a powerful force in keeping the public aware of traffic hazards and in pointing up the need of proved safety techniques in reducing highway accidents.

In the field of engineering, the mass of valuable data collected in the highway planning surveys begun in 1935, and later in the origin-destination studies in metropolitan areas, contributed immeasurably to a realization of the close relationship between design standards, traffic volume and safety. On these fact-finding surveys would be based the planning and design of modern expressways. More immediately, the survey reports were indispensable in improving the usefulness of existing roads and streets during the postwar reconversion period when shortage of materials, equipment and labour seriously curtailed new construction.

The Federal Aid Highway act of 1944 was a striking expression of the national interest in safe and efficient highway transportation. The act provided grants of \$500,-000,000 annually for the first three postwar years, to be used for the construction of primary highways, secondary farm-to-market roads, and major arteries in urban areas. The funds were apportioned on a formula basis, to be matched in equal amounts by the states.

Culminating the decade's constructive developments was the President's Highway Safety conference, held at Wash-

ington, D.C., in May 1946, which served to integrate activities of public officials and private organizations into the most practical over-all program ever achieved. The conference recommendations, co-ordinating the tested plans and techniques of the nation's best authorities, became recognized as a balanced traffic safety objective for state and local action throughout the United States. (See also DISASTERS.) (F. M. K.)

Accidents in Britain.-Comparisons of British accident figures during the decade could not be made with any accuracy because of conditions imposed by World War II. The usual official figures were, in many cases, either no longer published, or else considerably curtailed, especially in respect of non-fatal cases. Only figures of fatalities could therefore be taken as comparable. Totals of all accidental deaths were given in the annual publications of the registrars general for England and Wales, and for Scotland, but in 1946 no figures were available later than those for 1942. In the years before the war, the numbers of persons accidentally killed in Great Britain were between 18,000 and 19,000 a year, but in 1940 and 1941 the total rose to 25,000; in 1942, however, they dropped to slightly more than 21,000. A big increase was in miscellaneous accidents and this was no doubt influenced by wartime conditions.

Table II gives the number of persons killed (excluding deaths by enemy action) during the years 1937 to 1945, insofar as the figures were available.

Road.—The road accident position in Great Britain during the years 1937-46 was largely dominated by the influence of war-time circumstances. These imposed various conditions which tended to increase risks in some directions, while reducing them in others. The black-out which was imposed at the beginning of the war greatly added to the hazards of road usage, so that the year 1941 saw a new fatality record set up (9,169), despite restrictions on all but essential traffic.

After 1941, there was an improvement which could be accounted for by several reasons. The public had become more accustomed to black-out conditions; lighting restrictions for vehicles and in streets were to some extent relaxed; air raids were not so frequent. The basic gasoline ration was abolished in June 1942 and not restored until June 1945, and a gradually intensified safety publicity campaign was undertaken. As a result, the number

of persons killed on the road during 1945 was the lowest figure in the decade (5,256). The number of injured for the months of Aug. 1939 to March 1941 inclusive was not recorded.

In 1946, current figures were not available, but tendencies indicated an increase in the number of fatalities which was only to be expected with the return of traffic to the roads. In the case of nonfatal accidents, comparisons between the war and postwar years could not be accurately made as, with the police returning to more normal duties, more acci-

Not available. An accident is recorded when the sufferer is off work for three days or more.

10 dent

dents in which people were "slightly" injured were being reported. It was not certain what proportion of these came to the notice of the police in the war years. The pattern of road accidents remained much the same in war as in peace. Child fatalities were being reduced before the war, but the process was reversed when the war began, and despite improvement in the later war years, the number of children killed each year was well over the 1,000 mark. Young children between three and eight years of age, with the peak about five, remained as a most vulnerable class.

Factory.—War circumstances equally influenced factory accidents. Though the increases in both fatal and nonfatal accidents were disquieting, it should be remembered that the nation was mobilized for war production on an unprecedented scale. Many people worked in factories who were inexperienced, and many workers in the lighter and less dangerous industries were transferred to those in which more risk was involved. The decline in both categories, which operated in the later war years, indicated that some success attended the efforts of the ministry of labour and national service and other bodies to reduce the risks.

Mine.—In the mines there was an influx of inexperienced labour, but except for a relapse in 1941 there was a steady diminution of fatalities throughout the period, 1945 showing the smallest total in the period. Non-fatal accidents fluctuated to a larger extent, with a generally rising tendency.

(J. A. A. P.)

Acheson, Dean Gooderham

Acheson (1893—), U.S. government official, was born April 11, 1893, in Middletown, Conn. A graduate of Yale university in 1915, he received a law degree from Harvard university three years later. During World War I he served as a naval ensign. Acheson later became private secretary to Louis D. Brandeis, associate justice of the U.S. supreme court. He practiced law from 1921 to 1933, and in the latter year was U.S. undersecretary of the treasury, from May to November. Returning again to his law practice, he continued in this field until his appointment as assistant secretary of state, on Feb. 1, 1941.

After formation of the United Nations Relief and Rehabilitation administration in 1943, Acheson was selected as the U.S. member of the U.N.R.R.A. council. After the resignation of Joseph C. Grew, he was named undersecretary of state (Aug. 16, 1945). The following month, Acheson obliquely criticized General MacArthur by stating that the U.S. government, not the occupation force, would determine policy in Japan. The senate nevertheless confirmed Acheson as undersecretary by 69 votes to 1.

At the height of the world food crisis in the spring of 1946, Acheson suggested that the federal government should seize the grain required to meet its commitments abroad to avert mass starvation. With regard to the Argentine question, Acheson supported Spruille Braden, reiterating U.S. willingness to sign defense pacts with that country if in return the Perón regime would undertake to eliminate "axis influences." Acheson announced that U.S. policy favoured barring of foreign influences in China, but declared that the 20,000 U.S. marine troops there would remain in North China to guard supply lines from the coal areas to the coast.

Aden

A British crown colony and protectorate, the Aden colony is situated about 100 mi. east of the straits of Bab-el-Mandeb on the Arabian coast, latitude 12° 47′ N., longitude 45° 10′ E.; the protectorate is bounded on the east by Oman and on the north by the desert of Rub' Al Khali and on the west by the kingdom of Yemen. Area: Aden (colony), 75 sq.mi., Perim Island, 5 sq.mi., Kuria Muria Islands 22 sq.mi.; protectorate c. 112,000 sq.mi. Pop. (est. 1939) Aden and Perim 45,992 (Mohammedans 38,128; non-Mohammedans 7,864); Kuria Muria Islands 2,200; protectorate 600,000 (Mohammedans, no census ever taken).

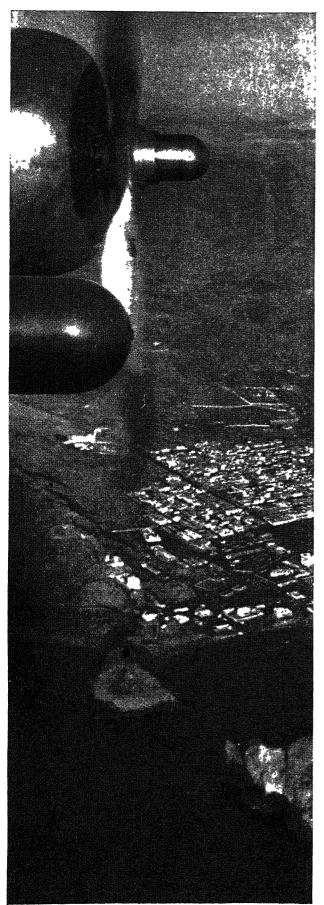

Governors (colony): Lieut. Col. Sir Bernard Reilly (April 18, 1931–Oct. 24, 1940); Sir John H. Hall (Oct. 24, 1940–Dec. 15, 1944); Sir Reginald S. Champion (after Dec. 15, 1944–).

Principal rulers (protectorate): Sir Abdul Karim Fadhl, sultan of Lahej; Sir Salih bin Ghalib al Qu'aiti, sultan of Shihr and Mukalla.

Under the provisions of the Government of India act, 1935, the administrative control of the Aden settlement was transferred from the government of India to the colonial office and on April 1, 1937, Aden became a crown colony. By the Protectorate order-in-council of 1937, the areas adjacent to the colony were transferred from the government of India to the British government. This was a normal administrative change and did not mean any lessening of the autonomy or responsibility of the chieftains.

On Aug. 13, 1937, a treaty was signed by the governor of Aden and the sultan of the Qu'aiti state of Shihr and Mukalla under the terms of which the British government was to appoint a resident adviser to the sultan whose advice the sultan agreed to accept on all matters except those concerning Mohammedan religion and custom. At the same time the governor addressed a note to the sultan in which he explained that it was by no means the intention of the British government to reduce the powers of the sultan and that the advice given to his highness in all matters of internal concern would be based solely on the adviser's views of the interests of the state and of his highness. A similar adviser treaty was signed by the governor and the Kathiri state of Saiun on March 2, 1939, and on the same date an agreement was signed by the British government and the sultan of Shihr and Mukalla and the sultan of Saiun reconstituting the agreement of 1918 which provided for mutual co-operation between these two states of the protectorate, the British government undertaking to settle any differences that might arise between them. Early in 1937, a general peace treaty for three years was arranged between the warring tribes in the Hadhramaut. The fact that there were nearly 1,400 signatories gives some idea of the unsettled state of the country. The treaty was extended for ten years in 1940, and on the whole was loyally adhered to. In the Qu'aiti state an efficient police force was built up, and by 1944 incidents

In the autumn of 1938 there was some trouble on the Yemen borders. Yemeni irregulars who had occupied Shabwa for about two months eventually surrendered to the protectorate authorities. There was further unrest in this region in 1939, but the king of Yemen intimated that he intended to adhere to the treaty of San'a signed by Great Britain and Yemen in Feb. 1934. These border

and tribal incidents were magnified by the German and Italian press and used as anti-British propaganda. In 1939, the centenary of the capture of Aden by a British naval and military mission was celebrated; a centenary fund for the establishment of infant welfare clinics and a scheme for permanent relief of the poor were started.

The sultans supported the Allied war effort loyally and to the best of their ability. Aden was one of the territories served by the middle east supply council, which was set up to look after the civilian needs of territories cut off from their normal source of supply. The governor was also a member of the middle east war council and the sub-committee of the middle east war council on supply and transport. The fall of Singapore and Java meant the loss of over £600,000 a year in remittances to the Qu'aiti state and this, added to the shipping problem, the loss of 50% of the working camels and the difficulty of getting food and its high price, had a grave effect on the protectorate, particularly the interior. A very severe famine hit the Hadhramaut in the spring of 1944 following a seven years' drought. The British government voted £300,000 for relief and rehabilitation and the R.A.F. provided air transport for grain. Hospitals were improvised and some 16,000 persons fed daily at emergency food kitchens. In the Qu'aiti state, merchants and government servants made voluntary contributions towards relief, and considerable sums were raised by local charity.

ATC plane over Aden, a station on the U.S. air transport command route from Miami, Fla., to Chabua, India, during World War II. Cargo was flown from Chabua over the Himalayas into China 12 Advertising

As in all other phases of the U.S. and British economies, World War II was the greatest influence upon the changes in markets, in advertising volume, in media, in methods of advertising and in distribution and retailing. Over the ten-year period 1937–46, however, there were also technical advances, valuable new information developed by research, and changes in the habits of the people, all of which had their effect upon advertising.

Fundamentally, there was a change in the prosperity of the U.S. In 1937, the nation was still climbing out of the great depression that began with the stock market collapse in 1929. In the autumn of 1937, for instance, there was a sizable recession in prices of securities and in business activity. The economy gradually improved, however. The national income that stood at \$71,500,000,000 in 1937 rose to \$96,857,000,000 by 1941 and to \$161,000,000,000 by 1945. This great prosperity affected all income groups, but especially those in the lower brackets who were less subject to the heavy taxation of war and were thus brought into the active spending groups.

Studies by the former National Resources committee for the year ended June 30, 1936, and by the bureau of agricultural economics and the federal reserve board for the year 1945 defined this trend. These studies showed that only 47% of the families in the U.S. had incomes of less than \$2,000 a year in 1945, compared with 81.5% in this lower bracket before World War II. Medium incomes, between \$2,000 and \$4,999, were received by 45% of the families in the later year, compared with only 16% before the war. It was also estimated that the average wageearner family had two-and-a-half times as much income left in 1945 after paying taxes and basic living expenses as it had in 1939. This was somewhat better than the average of nonagricultural families. However, the latter families were also better situated; it was estimated that farmers in 1946 had about \$15,600,000,000 for spending or saving, or about three times their prewar net income.

This rise in national income made possible expenditure of more advertising dollars. The increase was approximately \$450,000,000 from 1941 to 1945, according to figures compiled by L. D. H. Weld. Every medium benefited, with the exception of direct mail; radio and magazines scored the greatest gains. Figures for the two years are as follows:

Advertising Expenditures (Millions of dollars)

																						1941	1945
Newspapers.																						\$610	\$660
Radio	•							٠														225	400
Magazines .	٠	٠	٠		٠	٠		٠														180	330

																						\$1,920	\$2.386

Surveys by Standard and Poor's indicated that advertising would continue to grow, pointing out that from 1934 through 1940 there was a direct relationship between national advertising expenditures in five media and national income. The paper shortage that developed in 1941 distorted this relationship, but it was expected that with improvement in this respect, total advertising volume might resume its increases with those in national income, and that advertising expenditures might reach a total of \$3,000,000,000 annually, or well above the previous peak

of \$2,600,000,000 in 1929.

Newspapers.—During World War II, advertising in newspapers did not increase so much as advertising in other media—in radio and magazines, for instance—but it remained at a dollar value substantially higher than in other media. The rise was from \$610,000,000 in 1941 to \$660,000,000 in 1945.

One of the outstanding prewar developments in newspapers in the United States was an increasing willingness on the part of newspaper representatives to discuss the wide differentials between local and national advertising rates. There was also a growth in circulation. Total daily circulation rose from some 42,000,000 in 1941 to 48,300,000 in 1945, and Sunday circulation increased from 33,500,000 to 39,800,000 during the same years.

Two major ways in which World War II affected newspaper advertising in the U.S. were the newsprint shortage it created and the types of public service advertising campaigns that were engaged in by newspapers as part of their contribution to victory.

Restrictions on the use of newsprint were met by many expedients on the part of newspapers. Limitations on classified advertising were universal, effected through dropping out-of-town help-wanted advertisements, limiting the number of lines in each advertisement, reducing space for display and using agate type. The editorial side co-operated by compact writing and editing of news stories and other editorial material, reduction in features, slashing of comics, women's pages and financial news. Publishers preferred, however, to omit advertising rather than impair news coverage.

The next move in the conservation of paper was the curtailment of local retail and national advertising. Some papers adopted a 1,000-line ceiling and limited the number of insertions. Margins were cut down, and the number of editions was reduced. Optional insertion dates were urged upon advertisers.

Throughout the war, newspapers supported 50 or more government war and reconversion projects through editorial columns and advertising. From August 1943 through July 1945, war advertising in daily and Sunday newspapers in the U.S. totalled \$98,813,358, averaging more than \$4,000,000 a month. Chief projects were war bonds, \$42,597,445; Red Cross, \$6,252,678; armed forces recruiting (sponsored) \$5,133,385; waste paper and salvage, \$4,453,725. Total paid advertising with exception of war bond advertising was \$51,874,543; that donated by newspapers, \$4,341,370.

In its annual Blue Book, the American Newspaper Publishers' association in 1944 traced the growth of wartime advertising in newspapers and showed how it laid the foundation for reconversion by presenting factual case histories of campaigns by 75 advertisers and 56 advertising agencies.

In 1945, newspapers formed an organization to include both daily and Sunday papers for the promotion of use of newspapers for advertising in competition with other national media. National advertisers were offered the advantage of group rates for market coverage by regions or the entire country, each group of newspapers being sold as a single unit. In a similar bid for a larger share of advertising, the Weekly Newspaper bureau of the National Editorial association was created to improve weekly newspapers through better business practices in connection with advertising.

In Great Britain, by 1941, newspapers were reduced from 24 and 36 pages to 4-page size, and more than 170 publications disappeared from the newsstands by the end

of 1942, although 30 new periodicals were launched. Advertising copy in British newspapers during World Wai II stressed the fact that the nation was in a total conflict. Both government and private industry ran service advertisements. Advertising was still telling a sales story as changes and cheaper materials became necessary in products. In spite of the curtailment it suffered, advertising did a wartime job to find new ideas to build morale and help protect the people.

The end of the war did not remove rationing of paper in Great Britain, as it did in the U.S. Most of the big nationals, the Sunday and daily London papers, were still limited to four pages, and advertisements were still restricted to space three inches deep by two columns wide. This small space was forcing the advertiser to get his message into 35 or 50 words and the art director to achieve distinctive appearance and good visibility in spite of the small space at his disposal. An indication of the extent of this restriction in newsprint was that newspapers in Great Britain used only 290,000 tons in 1945 compared with 1,100,000 in a prewar year.

Another necessity forced upon the advertiser was the creation of advertisements that lent themselves to expansion horizontally or vertically and to treatment in sizes of diverse proportions. In a motor car advertisement, for instance, as many as 50 resizes might be used, a multiplicity of forms caused by lack of standardization of page sizes and column widths and the spaces of unusual dimensions offered advertisers by paper-starved publications.

Many British manufacturers who discontinued advertising early in the war started again as soon as the industrial scene adjusted itself. To cope with this increasing demand for space in smaller newspapers, the size of advertisements was reduced progressively from eight to four and one-half and finally to three inches by two columns, which was fairly standard in the first year and a half after the war. However, even this was not adequate, and the frequency of insertions had to be cut, so drastically that most publications soon limited insertions to one a month. This situation was not eased after the war, but rather it became aggravated as more manufacturers returned to advertising or as new advertisers arrived on the industrial scene.

Actually the allotment of one insertion a month was liberal, for emphasis was on less space. In the nationals a big advertiser could average no more than one insertion each three months, and in such important provincial papers as the *Manchester Guardian*, *Birmingham Mail* and *Liverpool Echo*, advertisers could count upon no more than two insertions a year. This allocation of space was watched carefully by advertising agencies to make sure that their clients did as well as competitors. However, apportioning of space proved to be invariably fair.

Papers might have eased their restrictions on advertising by increasing proportion of their space devoted to advertising, but generally they refused to do this. Legal maximum of advertising was 40%, but the Daily Express, for example, allocated only 14% of its space to advertising, and the Sunday Express 12½%. Other cases were the News Chronicle, 18%; Daily Mail, 17½%; London evening papers, 24%. The Times and Daily Telegraph, having had more pages in the first instance, allocated 38%, including classified advertising.

An important exception in reference to size restrictions was government advertising. During the war such campaigns used copy as large as two columns 11 in. deep, but the average size allotted to the government was about two columns by eight inches. This space was reduced to five inches after the war because of pressure by manufacturers

Will change the three productions the second of the second

Prize-winning U.S. advertisement of the 1938 Annual Advertising awards

for more space for their own use. However, government advertising continued an effective instrument for influencing public opinion toward waste of food, saving, spending, recruiting, safety on the roads and other matters.

Lack of foreign exchange forced the government after the war to urge industries to export certain specified percentages of their products, and the resultant shortages at home were reflected in advertising. Manufacturers often used advertising not to get immediate orders, but rather to keep their names before the public, to keep customers in contact with dealers and to explain delays in deliveries or production. Associations and industry-wide advertising groups were active, typical campaigns being those conducted by the Scottish Oatmeal Millers' association and the Brewers' society. The latter was seeking to create goodwill for inns and taverns. (See also Newspapers and Magazines.)

Radio.—Radio scored one of the biggest gains of any advertising medium during the war, its revenues rising from \$225,000,000 in 1941 to \$400,000,000 in 1945. However, there were substantial increases in costs also. Cost of talent was approximately 50% greater toward the end of the war than it was in the beginning; in the 1940–41 season, for instance, aggregate talent costs for network and commercial programs were in the neighbourhood of \$30,000,000 for nighttime and \$7,500,000 for daytime programs, while in the 1943–44 season corresponding costs were \$45,000,000 and \$10,000,000.

Scarcity of good network time forced many national advertisers into spot radio. Effectiveness of their experiments was indicated in the rise of spot radio sales from \$37,000,000 to \$59,000,000 between 1940 and 1943. Moreover, advertisers who found that they could not get all the space they wanted in their local newspapers turned to their local radio stations, with the result that such time sales increased \$20,000,000 in the first two years of the war.

Commercially sponsored television programs were intro-

"Hello Mom, It's Me!"

Among the 100 advertisements judged to have contributed most to the U.S. war effort in 1945 was this advertisement prepared for the Bell Telephone system. Awards replaced for the duration of the war the former choice of a "best" advertisement for the year

duced in 1941. On July 1, 1941, sponsored programs were televised by CBS, Dumont and NBC in New York city. Sponsored television, as well as frequency modulation (FM), became one of the first casualties of the war, and it was not till the conclusion of that period that interest was revived. Both were still in the stage of being young industries.

In mid-year 1946 it was announced that a \$60,000,000 television motion picture production centre for networks, radio and telecasting stations, national advertisers, advertising agencies and independent producers would be built in the New York metropolitan area. The "Telecity" was to cover 1,000 acres, include 24 large motion picture studios and every type of maintenance building, service and facility required.

In the prewar years, an interesting development in 1938 was a study by the joint committee on radio research of the methods of determining the areas in which programs of individual broadcasting stations were heard. Advertising messages became more closely integrated with entertainment features in this period, and transcriptions came into wider use. In the United Kingdom a poll of 500,000 listeners revealed that 95.6% preferred sponsored programs, originating at a continental station, to non-commercial programs of the British Broadcasting company.

By 1940, advertisers in the U.S. were spending \$200,000,000 for time on radio stations, and it was estimated that there were some 52,000,000 radio sets in use. In June of that year the Associated Press approved full commercial broadcasting of news. During the year the Federal Communications commission approved FM. FM made more stations possible than the 550- to 1600-kilocycle band permitted, and provided static-less reception.

In 1941, advertisers in the U.S. spent \$107,500,000 for time on the three major networks, an increase of 11% over the previous year. They spent \$35,000,000 on programs, an increase of 24%. This disproportionate increase was caused by some shifting from quiz programs, which were relatively inexpensive, to more costly variety shows. News broadcasts increased greatly with the war, and advertisers capitalized on this greater interest by increasing their commercial sponsorship of news reports. Both stations and sponsors contributed time generously to the defense and war efforts. It was estimated that stations on the average devoted 760 min. and 227 announcements to the defense efforts in the month of July 1941. With entry of the U.S. into the war, most stations entered upon a 24-hr. schedule and broadcast news every hour or half hour.

British commercial radio broadcasting was virtually nonexistent before the war. The BBC, owned by the government, had never permitted sponsored commercial programs, and the two chief radio stations on the continent which accepted commercial programs for British advertisers, ceased to operate because of the war. These were Radio Normandy and Radio Luxembourg.

Radio in the U.S. saw a great year in 1944, with estimated gross time sales of \$350,000,000. It was figured that the amount of time and talent devoted to the war effort during the year was \$66,141,000.

The first year, 1946, after the war saw confusion over broadcast measurement services. After 1942, when the Cooperative Analysis of Broadcasting, Inc. (CAB) fundamentally changed its research methods, broadcasters were faced with the dilemma of choosing between the two major radio audience rating services, C. E. Hooper, Inc., and CAB, both of whom claimed to measure the same thing and use the same basic method, but between whose ratings there was a marked difference. In the summer of 1946, the CAB decided to suspend its operations, and later in the year voted itself out of existence.

In mid-1946 the Broadcast Measurement bureau announced that it would begin to provide information on radio station and network audiences. BMB was a cooperative enterprise supported by the American Association of Advertising Agencies, the Association of National Advertisers and the National Association of Broadcasters. The new service would provide information on sizes and locations of station and network audiences and was to be published in two forms, station audience reports and a U.S. area audience report.

The composition of radio programs was about the same at the end of the war as it was at the beginning, although wartime security regulations cut "audience participation" shows one-third. Drama occupied the greatest percentage of time on the air, with variety shows, commentators, news and talks, popular music, familiar music and classical music following in that order. An obvious change was the advent of the singing commercial, conspicuous examples being the Pepsi-Cola song and "Chiquita Banana." (See also Radio.)

Magazines.—Expenditures for advertising space in magazines in the U.S. during World War II were almost doubled, increasing from \$180,000,000 in 1941 to more than \$300,000,000 in 1945. They also emerged from the war with greater circulations than before it. These gains were due in large part to the curtailment of other forms of entertainment for magazine readers. The first year after the war saw a considerable number of magazines either announce new higher advertising rates and circulation guarantees, or indicate plans to do so. In this period there were also more than 50 new magazines launched, accord-

ing to the Magazine Advertising bureau, appealing to a wide range of interests.

The gain in the average net paid circulation of 21 leading magazines was 12% in the period from 1941 through 1945, according to the Association of National Advertisers. This report also revealed that the war had reversed sharply the trend from newsstand sales to subscription that had prevailed during the 1930s. It showed that subscription circulation gained 62% in the years 1930-40, but only 4% during the war period. Newsstand sales showed the opposite development, having gained only 8% during the 1930s, compared with 55% after 1940.

One of the outstanding developments of this period was the growth of comic books. The first of these appeared in 1933, but they had a spectacular growth during the war, and by the end of 1946 one publisher, with 26 books or titles, boasted circulation of 26,340,000.

A study conducted by the Market Research Company of America in 1944 revealed that of all homes interviewed, whether with or without children, nearly three out of four had one or more members who read comic magazines. Of children 6 to 11, for example, 95% of boys and 91% of girls read comic books regularly. A study by Stewart, Brown associates in 1945 showed that children readers of comics had very definite preferences for brands of goods. Not all publishers of comics accepted advertising, but those who did were careful to see that claims made in advertising could be substantiated, as such a large part of the circulation was to children. At army post exchanges throughout the country, comic books outsold all other magazines ten to one.

Even before the war there were gains in circulation of magazines, however. Twenty-one leading magazines issued a total of 1,103,000,000 net paid copies in the 12-months' period ending June 30, 1941, a gain of 5.5% over the corresponding 1940 period. Two or three magazines began to distribute their copies in substantial numbers by air express to South America.

During the first year of U.S. participation in the war, circulation continued to gain. Net paid circulation of 78 leading magazines increased 4,285,513 or 7.2% during the first six months of 1942 over the corresponding period in 1941. Many magazines reached all-time highs during the year in both circulation and revenue, and others reported substantial gains. During these months, an analysis of 30 magazines showed that 48% of nonfiction content and 65% of editorial matter were devoted to war themes. Both editors and advertisers furnished information highly important to readers and co-operated in prompting conservation and building morale. There was direct co-operation with the government in distributing messages with regard to purchase of war bonds and stamps, and some sponsored nutrition programs or urged consumers to do their part in making home, community and country ready, efficient and strong, or to buy carefully and avoid waste.

The following year showed continued gains. In spite of nationing of paper in 1943, magazines as a whole carried the largest volume of advertising in their histories. Although \$50,000,000 of advertising was refused in 1943 because of paper shortage, 105 magazines reported gross revenue of \$228,000,000, compared with \$174,582,000 in 1942 and \$196,687,000 in 1929, the year of the great boom. Ten publishers, including The New Yorker, Newsweek and Life, published and distributed free of charge miniature editions for use of servicemen overseas. These overseas editions carried substantially the same editorial matter but no advertising.

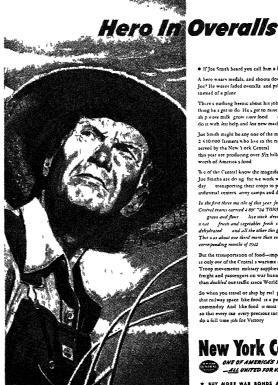

For these magazines checked by the Publishers Infor-

mation bureau and reporting advertising revenues of \$228,000,000 in 1943, the revenue was \$270,000,000 in 1944. Although the magazines had to operate under the same paper restrictions as in 1943, they were able to increase advertising considerably by reducing weight of stock used and by closer trims. However, many publications had to refuse demands for space. Advertising volume in business papers also increased, rising 24% during the year. Time magazine expanded its editions to 20, 4 for the U.S. and 16 for other countries.

In 1945 magazine advertisers increased their volume to \$300,000,000, compared with \$270,000,000 for 1944, although there were still paper restrictions. An outstanding accomplishment was the promotion of Seventh War Bond sales through more than 3,000 cover displays and full-page advertisements donated by the magazines and advertisers. Magazines continued to co-operate with the government on all war and peacetime campaigns, including the Economic Stabilization program.

Outdoor.-Outdoor advertising was a medium considerably affected by the war. It was affected by shifts in population incident to the situation of war industries and military establishments, by dimouts against submarines, decline in motor travel and shortages of manpower, including that needed for traffic audits. However, the lifting of dimout regulations and the end of gasoline rationing after V-J day quickly stimulated U.S. interest in this medium. During 1945, there was an increase in national advertising volume of 40% over that for 1944. A greater part of this growth came from automotive and accessories fields. According to Traffic Audit bureau figures released in the fall of 1945, effective circulation of outdoor advertising

Advertisement prepared for the New York Central system, one of the 100 advertisements adjudged to have made the greatest con-tribution to the U.S. war effort in 1943

If Joe Smith heard you call him a hero he d laugh A hero wears medals, and shoots down Zeros. But Joe? He wears faded overalls, and pilots a plow

There's nothing heroic about his job to Joe. It's a thing he's got to do. He's got to raise more hogs ship nore milk grow riore food and he's got to do it with less help and less new machinery.

Joe Smith might be any one of the more than 2 410 000 farmers who live in the rich farming area served by the New York Central whose farms this year are producing over 3½ billion dollars worth of America's food

We of the Central know the magnificent job these Joe Smiths are doing for we work with them ever day transporting their crops to processing andustrial centers army camps and docksides

In the first three mo this of this year for example.

Control trains carried 490° 24 TONS of farm products

grain and flow. Inc stack drawed and careed

nest front and textables fresh canned and,

deliphraced and all the other things people and.

This was about our three three things to people and,

This was about our three three this in the

corresponding months of 1942.

So when you travel or ship by rail please remember that railway space like food is a perishable commodity And like food it must be conserved

in 206 cities was 23% greater than at the time of the previous audits during 1938–42, although there were wide variations within geographical sections.

During the early 1940s, progress was made in placing the purchase of outdoor space upon a more factual basis, similar to the purchase of space and time in other comparable media. Moreover, the growth of supermarkets and self-service chain stores and the expanding use of open display in all types of retail outlets reduced or eliminated influence of sales clerks on consumer purchases, and placed greater emphasis on product and label identification and consequently on the use of outdoor advertising in shopping centres or on roads leading to them.

In 1939, for example, it became possible for the first time to buy outdoor space in nine different intensities or degrees of coverage, in comparison with the three available formerly. Also new was the guaranteeing of minimum circulation, based on traffic counts. Statistics on circulation of outdoor advertising grew to cover 65% of all advertising space in 17,000 communities.

In 1940, measurement of outdoor circulation by the Traffic Audit bureau was extended to all members of the Outdoor Advertising association. This brought an improvement in outdoor plants and an audited circulation increase of 7.5% for 1940 compared with 1935.

Practically complete standardization of structures and services came by 1941. This resulted partly from the activities of the Outdoor Advertising association and partly from the extension of the services of the Traffic Audit bureau, which audited practically every outdoor plant in the U.S. every three years. Each panel was given a rating by the bureau, and plant operators undertook to re-locate those with low ratings to spots where their ratings would be improved.

Effect of the war was felt in an extreme way in 1942, especially because of reductions in motor travel, dimouts and shifts in population to war production centres and military camps. These facts, and the shortage of manpower available to make the counts, interrupted auditing of outdoor circulation. However, there were some indications that circulation was greater than ever before, that lessened motor travel had been compensated for by greater travel on foot and in buses and other such conveyances.

Traffic Audit bureau tabulations were resumed in 1943. Reports for the May 15-June 30 period, based upon 105 cities, showed that in comparison with the 1939-1941 audits, 65 cities gained in effective circulation, 36 decreased, while 4 remained the same.

For the spring of 1944, the effective circulation of outdoor advertising in 181 cities was 8% greater than it was at the time of previous audits from 1938 to 1942. Of the 181 cities surveyed, 116 showed increases in effective circulation. After the last audits, a shift in modes of travel had taken place, with pedestrian travel increasing 75%, streetcar and bus 70%, and automobile and truck traffic decreasing 9%.

During the war, outdoor advertising carried treasury and civilian defense appeals to the public, sponsored by local and national advertisers and by the outdoor medium itself without any cost to the government.

Direct Mail.—Expenditures on direct mail fell off; for one reason, there was a reduction in novelty mailing pieces, probably because of their greater cost. The medium changed somewhat in nature. Printed promotion geared itself largely to the war effort, and users of direct mail tied in their appeals with the various major wartime projects. A guide book which was helpful to users of printed promotion in this effort was issued by the Graphic Arts Victory committee. This committee was also helpful to all types of organizations in successfully using the convention-by-mail method, resulting in hundreds of conventions being cancelled and thus contributing greatly in relieving demands on transportation. The committee also pointed out many ways to make paper go further in use. Catalogues, directories and shopping newspapers were assigned paper quotas limiting them to 85% of 1941 usage.

Restrictions caused direct mail volume to shrink during the first part of 1945. Near the end of the year, however, printers were flooded with orders for new catalogues and promotion of all kinds.

A study of direct mail pieces, catalogues and technical books showed that illustrations, layout, copy and physical size of mailing pieces influenced reading by recipients and indicated that the effectiveness of direct mail was dependent primarily upon advertisers. Among executives, 63% preferred small mailing pieces, while 95% of the purchasing agents interviewed liked uniformity in size of catalogues.

After V-J day the Graphic Arts Victory committee ceased to function, having completed successfully its function of putting printing, lithography and all devices of the graphic arts into the war effort. Millions of printed promotion pieces devoted to war and victory campaigns attested their worth in the war program.

Transportation Media. — Transportation advertising flourished during the war because of the lessening of automobile traffic caused by gasoline and rubber restrictions and the great increase in the numbers of war workers who had to use commercial transportation. During the first year of the war alone, the number of passengers on buses and trolley cars increased to a total of 20,000,000,000, and the volume of transportation advertising grew 33%.

In 1940 an innovation in car card advertising was the new space offer of 11 by 28 inches at the same rate as the old standard 11 by 21 inches. In March 1942 the National Association of Transportation Advertising Inc. was formed to co-ordinate the work of the industry, to maintain standards of practice, and to engage in research and promotion.

In 1943, transportation showed the largest percentage gain of any major medium of advertising. Volume at \$10,000,000 was 20% higher than in 1942. Many cities were completely sold out, with practically all space reserved for months ahead, and rate increases were prevalent. Most national advertising continued to be on branded goods, chiefly foods and drugs. The industry's war campaign pool contributed approximately 100,000 free spaces a month to the government for war messages. Carded vehicles increased slightly, numbering 85,000. Riders that year exceeded 22,000,000,000. In 1944, the volume increased to an estimated \$13,000,000, with most systems carrying about all the advertising they could accept.

Riders and revenue continued to rise in 1945, with transit riders numbering more than 23,000,000,000, an all-time high, and revenue being about \$16,500,000. This rise was curtailed toward the end of the year with suspension of wartime gasoline restrictions. At the end of the war the transportation advertising war campaigns pool was discontinued, but 50,000 car card spaces a month were given to the Advertising council for peacetime public service campaigns. Surveys showed that eight out of every ten adults were riders and exposed to the displays.

Copy and Layout.—During the decade 1937-46, the outstanding changes in copy and layout resulted from the

war. Shortages in paper in Great Britain reduced the advertising space available to an individual advertiser to miniature size, necessitating great compactness in copy. Need to resize advertisements to fit the multiplicity of sizes of space offered advertisers, made it necessary to have flexible layouts everywhere. War themes and subjects incidental to war occupied a dominant part of advertising

Over the whole period, readership studies became increasingly popular. Advertising technicians learned by the study of these reports to prepare advertising which had greater readership. Individual advertising agencies reported that by paying particular attention to developing readership they had increased it for some of their clients by as much as 100% to 150%, although the average over the period was nearer 24%. Studies of types of copy treatment showed that advertisements about people and "How To" advertisements were read most, while treatment that featured striking events, broad general assertions, or advertisements about products as such were less well read on the whole.

Toward the end of the period there developed a desire on the part of advertisers and their agencies for studies which not only showed them the relative readership of various advertisements, but also indicated the relative power of advertisements actually to make sales.

As early as 1937 there was noticeable a tendency toward more direct and terse copy, a tendency obviously borrowed from radio broadcasting. Humour became more prevalent, and the comic strip form of advertising came to be used, with some 300 newspapers in the U.S. arranging to publish such advertisements on their comic pages. Following the social security programs introduced into the United States in the 1930s, there was greater awareness on the part of industry of its social responsibilities and a greater tendency to explain to the public the ways in which individual business organizations were carrying out their contracts with the public. This led to the development of goodwill and institutional advertising. In the U.S. large manufacturers, banks, insurance companies and public utilities emphasized this type of appeal. In the United Kingdom, the post office and other government agencies used institutional advertising.

Technical changes included shorter and more rhythmic headlines, bleed-type illustrations, rotogravure and other varieties of colour advertising used more extensively, and more photographs reproduced.

In layout the trend toward photograph and caption developed to the point where it was common to find several photographs in an advertisement where formerly one or two were considered adequate. Moreover, photographs largely replaced line drawings. The question-and-answer technique was transferred from radio advertising to printed advertising. In spite of the war, humour persisted to a marked degree in British advertising. However, British copy themes began to be built around new arguments as to why products were good in wartime. Many advertisers of products such as motor cars, whose sales were controlled, continued advertising in order to keep their names before the public, but devoted their space to institutional and patriotic messages. Advertisers of such products as gasoline, motor oils, tea, margarine and other products subject to government pooling and control, discontinued advertising completely.

By 1941, U.S. advertisers had not been turned in any substantial fashion from product selling, and in a survey it was estimated that 96% of advertisements were directed definitely at selling goods and services. The remaining 4% consisted of advertisements either showing a man in uniform using the product or a military background, or else were institutional in that they merely described the contribution of the company to the defense effort. Some companies, although they had no goods to offer to the public, continued to advertise their products on the ground that they would be available as soon as the war was over.

After the United States entered the war, as materials became scarce or unavailable for the manufacture of civilian goods, and as more and more industries converted all their energies toward war production, the nature of advertising also changed. The government recognized the usefulness of advertising, and used paid advertising extensively in promoting the recruitment of army and navy personnel, in selling war bonds and stamps and in publicizing various drives. Individual companies also paid generously for advertisements in connection with salvage drives, grease and fat conservation and similar campaigns. All advertising took on a patriotic fervour, illustrated by pictures of tanks, planes and military men.

There was a bit of confusion early in the war years as companies tried to be both patriotic and still tell their individual stories. Gradually the advertisers began to tell, in factual statements, what U.S. industry was manufacturing and the job that the United States as a nation had to do. The cartoon-continuity technique, which had proved so successful in prewar years, fell off considerably, as it did not lend itself so readily to the dignity that advertisers felt should accompany such messages.

Wartime advertisement, prepared for the war finance division of the U.S. treasury department to promote the sale of war bonds. It received an award as one of the 100 advertisements which made the greatest contribution to the war effort in 1943

YOU WRITE A LETTER to a Prisoner of

nd when you sit down to write tell him buy your share of War Bonds last pay day Dear Joe 'you might say, the old topo

out Joe might not unde ally if he a shivering in a da Let s try again Dear Joe I ve been w hard and haven t had a vacation in over a y Hell better cross that out, too They of tions where Joe's staying

Well what are you waiting for? Go ahead, write the letter to Joe Try to write it anybow

The tone of advertising improved in 1943. Much of the copy became more realistic and informative. Advertising became aware of public and government sentiment against commercializing patriotism in print and boasts of contributions toward winning the war.

As the war drew to an end, as a sellers' market continued but the prospect of a buyers' market became likely, some advertisers abandoned the public relations, institutional types of advertising they had perforce used during the war and turned to selling copy. There began to be greater use of product-selling copy in industrial advertising. During Sept. 1944, 77% of advertisements were devoted to selling products or services, an increase of 50% over April, while war copy dropped from 22% in April to 12% in September. Efforts to bridge the transition to peace produced unusual and worthwhile campaigns dealing with product shortages, social and political problems and appreciation of others' activities in the war effort.

War and Advertising.—U.S. business contributed to the war effort more than \$1,000,000,000 of advertising space and time in three and a half years. It participated in more that 100 homefront campaigns in co-operation with 27 government departments and agencies, informing the nation about war bonds, armed forces, V-mail, merchant marine, civilian nurses, food rationing, salvage and civilian services. Business organizations contributed an estimated \$350,000,000 in advertising space and time in support of war bond promotion alone.

A survey by the American Marketing association in 1943 showed that 86% of management and advertising executives believed business had a responsibility in disseminating information to the home front, expressing a strong preference for voluntary contributions of advertising space and time, rather than appropriation of government funds for this purpose.

Much of this wartime advertising activity was under the leadership of the War Advertising council, which was organized in the spring of 1942 by advertisers, advertising agencies, magazines, newspapers, direct mail, mechanical craftsmen and other branches of advertising. The council was designed to offer to the government the volunteer services of every type of talent and experience relative to the creative or administrative phases of advertising, merchandising and marketing.

After V-J day, the organization changed its name to the Advertising council, and continued its efforts in peacetime by taking over the administration of pooled media facilities formerly handled by the Office of War Information. All branches of advertising continued financial support to the council.

In 1946 the council adopted three campaigns on which to work: atomic energy, world trade and inter-group understanding.

In Britain, early in the war, advertising continued in considerable volume for products not greatly affected by government restrictions and which had "relief" and "escape" appeals, such as cigarettes, soap, liquors, cosmetics, beauty preparations, household aids and sweets. As restrictions became more severe, this advertising stopped. Advertising agency and publication offices were decentralized into units in different sections, so that if one was bombed activities could go on in the others. All available advertising media were put to use, because of the newsprint shortage.

Most newspapers and magazines continued, and the war gave additional interest to magazines of the picture type,

a trend which was also evident in the U.S.

The British government came to make wide use of newspapers, magazines, posters, billboards, films and radio in its efforts for recruiting, air raid precaution work, food conservation, war financing and maintaining morale. Government programs were handled through British advertising agencies.

Legislation.—The Miller-Tydings act was passed in the U.S. in 1937, providing that the federal anti-trust laws should not invalidate contracts between manufacturers and distributors fixing retail prices in states where such contracts were permitted by state fair-trade acts. Forty-two of the 48 states had passed fair-trade acts, permitting but not requiring manufacturers to fix minimum retail prices. By encouraging competition between national and private brands of merchandise, this legislation undoubtedly increased advertising for both types.

In 1938, the Wheeler-Lea act prohibited any advertising or merchandising practice unfair to a competitor, a consumer, or the general public. It was unnecessary under the act to prove that advertising had injured a competitor, but merely to show that it was misleading in a material respect. The Food, Drug, and Cosmetics act supplemented the Wheeler-Lea act by prohibiting misrepresentation of foods, drugs, and cosmetics, or the use of harmful ingredients.

British advertising was affected to some extent by war legislation. Producers of gasoline, tea and margarine were forced to pool their products, with the result that brand names could not be used, and advertising was therefore ineffective.

In the U.S., the first national labelling law was passed in 1940, calling for correct labelling of wool products.

Research.—Activities in advertising research carried on by specialized organizations, publications and advertisers in the United States increased throughout the decade 1937–46. A joint study was continued by the Bureau of Advertising of the American Newspaper Publishers association and the Advertising Research foundation to determine current newspaper reading habits. Qualitative measurements of the effect of radio programs upon audiences were improved, and figures on radio ownership, listening habits and location of receiving sets were made available to advertisers and their agencies.

An outstanding research project completed in 1941 was the four-year study of the economic effects of advertising under the direction of Neil Borden and an advisory committee of the Harvard graduate school of business administration.

During the ten years, the continuous measurement of readership of advertisements in magazines, known as the Advertising Readership service, conducted by Daniel Starch and staff, increased the number of magazines included in this survey from 18 to 31. In this continuing program, approximately 120,000 individual interviews were conducted each year.

A survey in 1943 by the Association of National Advertisers revealed that the public wanted modest, informational advertisements with a description of postwar products, data on war-winning projects and information on how to co-operate with them. The study also showed that persons were aware of the contribution business was making in the war effort and that they wanted companies to continue advertising because names should be kept in the public's mind. Forty-seven per cent believed advertised products were superior to those not advertised. Another study made among farmers showed that three-quarters of those questioned thought: (1) business advertising helped

them; (2) private management ran business better than government could; (3) government-owned plants should be sold to manufacturers after the war and not run in competition with business.

In 1944, looking forward to postwar problems, the Committee for Economic Development published two major research studies on problems of reconversion. And in order that government and business might have accurate facts on the nation's economic status to ensure transition to a high level of postwar production, congress approved an appropriation of \$9,672,000 for a fact-gathering program to provide data on manufacturing, distribution of employment, income and spending.

The Interstate United Newspapers, representatives of more than 100 publications in the Negro group, released preliminary data on a Negro consumer study made in Washington, D.C., covering information on owners and renters of homes, radio sets, insurance and on brand preferences.

In 1945 the Pacific Advertising association sponsored a program covering fundamental economic conditions which provided a postwar outlook for marketing and a background for market planning in the west.

Toward the end of the decade, increasing numbers of studies were made by research organizations, manufacturers, publishers and advertising agencies in the various fields of marketing and advertising. These studies included use of products in selected areas, and observation and reading of advertising. Although there was some criticism of research as being overdone and over-extended, this was more than offset by suggestions to the effect that increasing effort should be put to making proper and adequate use of the results of research.

Consumers.—In the United States, the National Retail Dry Goods association sponsored in 1937 the Consumer-Retailer Relations council, whose purpose was to encourage accurate, informative labels, uniform terminology meaning the same to dealer and consumer, and truthful local and national advertising. The group was composed of representatives of national women's organizations, large retailers, manufacturers and federal government bureaus.

A committee on consumer relations in advertising was established early in 1940 to engage in fact finding and research on the economics of advertising and consumption. Also early in that year the Institute of Standards, Inc., was founded as a co-operative solution to problems resulting from the consumer movement. This movement had grown to such proportions by then that no manufacturer could afford to ignore its influence. Consumer pressure caused greatly increased consumer activities among government agencies.

The year 1941 witnessed a widening interest on the part of consumers in their economic role as such. Heading their activities was consumer education, including choicemaking, market selection, use and care of products and emphasis on the relation of the consumer to the economic society. Numerous educational units were organized, including local consumer groups, co-operatives, community centres, and defense-inspired consumer councils. Emphasis was placed on conservation and reduction of waste. Consumers were educated to select essential goods, to have more concern for the use and care of appliances, to salvage used materials, to understand the importance of national resources, and so on. Demand for standards increased with the scarcity of goods. Consumers became less reformist toward business and more willing to co-operate with business groups, as witness the Committee on Consumer Relations in advertising and the National Consumer-Retailer council.

One answer to consumer complaints was the growth of informative labelling and advertising. The latter part of 1942 saw the beginning of experiments in self-selection of merchandise by the consumer in practically all types of department and speciality stores, with open displays accompanied by printed information.

As the war progressed, by 1943 for instance, copy for the woman consumer reached basic realism in the face of shortages. Food advertisements gave as much information about food nutrition as food editorials, and gave as well helpful information on how to make food go far, how to maintain family health, how to get variety out of stocks on grocers' shelves.

Shortages also affected the buying habits of consumers, and a survey showed that 58.8% of housewives went to more stores to obtain food products and 55.7% went to more stores to buy meat. Branded products became menaced by two factors; (1) unavailability of branded goods and the offering of substitutes; (2) compulsory grade labelling in fixing price ceilings. Brand Names Research foundation was established early in 1944 to educate persons on the basic idea behind trademarked products in the clothing and food fields.

A study by the Committee on Consumer Relations in advertising of the 14 most frequent copy themes showed highest approval by readers for copy that told them how to conserve and yet get the most out of one's equipment and clothing and how to stretch scarce foods and plan nutritious meals. Another study by this committee in 1945 showed that all media of advertising had materially increased their informational content to consumers on the proper use of products.

By unanimity reached among both canners and distributors on descriptive labelling techniques, additional product information was to be given on food labels.

20 Afghanistan

An independent kingdom at the heart of Asia, Afghanistan lies between the U.S.S.R. in the N. and India in the S.E.; on the W., Afghanistan has a large common frontier with Iran (Persia) and on the E. a narrow one with China (Sinkiang, or Chinese Turkestan). Area: c. 270,000 sq.mi.; pop. (est. 1937) 9,910,000; (est. 1946) 12,-000,000. Chief towns (pop. est. 1946): Kabul (cap., 206,-200); Herat (75,600); Kandahar (77,200); Mazar (41,900); Maimanah (25,700); Baghlan (24,400). The government of Afghanistan is a constitutional monarchy; supreme legislative power is vested in the king, the assembly of nobles (Majlis-é-'alié-'Ayan) and the assembly of representatives (Shura-yé-Milli); the former are nominated for life by the king, the latter (100 in number) are nationally elected for a period of three years. At irregular intervals, to discuss important affairs of the state, the king summons the Afghan national assembly (Loya Jirga); its last meeting in the decade under review was in 1941, when c. 1,000 representatives were present. King: Mohammed Zahir Shah, who succeeded to the throne in 1933 after the assassination of his father, Mohammed Nadir Shah. Prime minister: Sardar Muhammad Hashim (1930-1946); Sardar Shah Mahmud (after May, 1946).

Recovery from Civil War.—In 1937, Afghanistan was still suffering from the calamitous effects of the civil war of 1929. The country's internal policy, therefore, was based on national reconstruction. In the first place, various efforts were made towards the establishment of security and national unity of all classes, in order that the country should be ready to receive the plans for fresh reconstruction which were envisaged.

The second stage was to reinforce the country's economic structure and to spread modern education. This was felt to be not only essential to Afghanistan's material and spiritual progress and advancement in the future, but also a dire necessity in compensation for past losses.

In the economic field, the Afghan government succeeded in 1939 in drawing up a comprehensive plan, a great part of which, however, could not be realized as a result of World War II. In 1945, this plan was resumed with the necessary modifications. The essential points of the plan were: (1) the restoration of Afghanistan's direct commercial relations with European and U.S. markets, (2) the stabilization of Afghanistan's currency and the protection of commerce and industry by the establishment of banks and trading companies; (3) the extension of agriculture with a view to increasing exports (especially cotton); (4) the creation of new industries so as to reduce imports.

Foreign Markets.—Before World War II Afghanistan traded with Persia, Russia and India and (via the last) with many European countries. In 1937 the Afghan minister for economic affairs visited Great Britain to examine the possibilities of extending trade with that country, but did not achieve complete success. During the war, for the first time, Afghanistan established trade relations with the U.S. via India. Before the war she traded unilaterally with Japan, importing only Japanese goods. She also traded with Great Britain on a small scale. As a result of the war, Afghanistan's karakul skin business, her only trading interest in London, was closed and transferred to the U.S. In 1936 a commercial agreement for three years, worth \$10,000,000, was signed by soviet and Afghan trade organizations; this connection was renewed in 1940 and again in 1942. Similarly, in 1936 a commercial agreement was signed between Afghanistan and Poland, which established good relationships between the two countries and resulted in the setting up of the first Polish consulate in Kabul.

In 1938, Afghanistan signed a trade agreement with Italy and in 1939 with Germany. In 1938 a conference of Afghan merchants and German representatives was held in Kabul, as a result of which the *Deutsche Lufthansa* became the only air line to use Kabul airport.

Subsequently, an Afghan-Japanese commercial society was founded and several Afghan students were sent to Japan to study economic problems. In March 1941 an Afghan mission went to Tokyo. In 1943 a commercial agreement was signed with the United Kingdom Commercial corporation.

Although World War II postponed a great part of the plan to strengthen Afghanistan's economic structure, yet the country was able to show a certain increase in exports.

Before 1936 a great part of Afghan trade was carried on by individual merchants, with the result that Afghan national interests were not always sufficiently defended. Consequently the government endeavoured to form trading companies. By 1940 there were 15 such companies with a total capital of \$29,953,000 (389,000,000 afghanis); by 1946 their total capital was \$74,425,000. (Afghani = 9.2 cents U.S.)

Foreign Policy.—The basis of Afghanistan's foreign policy during the period 1937–46 was the maintenance of friendly relations with her neighbours. Constantly observed by the latter, she strove continually to strengthen and reinforce these bonds and show herself desirous of extending her friendship to all nations. In accordance with such a policy and with her pacific intentions, Afghanistan declared her neutrality in World War II and remained faithful to this undertaking, not allowing the smallest occasion for injury to her political relations with friendly powers. In 1942, diplomatic relations with the U.S. were initiated and ministers exchanged. In 1944, diplomatic ties with China were strengthened, and an exchange of ministers between the two countries resulted.

On June 13, 1946, Afghanistan concluded its most important diplomatic agreement with the soviet union. It related to the definition and delineation of the frontiers between Afghanistan and the U.S.S.R., and was signed in Moscow by Vyacheslav Molotov and Sultan Ahmad Khan. the Afghan ambassador to Moscow. Under this agreement, the frontier line along the Penj and the Oxus rivers, where navigable, followed the deepest soundings; where not navigable, it followed the midstream. The attachment of the islands in these rivers, in accordance with international waterway practice, was to be dependent on the above methods of drawing the frontier line: the island of Darghah remained in the possession of Afghanistan, and the island of Aral Paighmar remained in the possession of the soviet union. By the agreement, the land frontier drawn in the 19th century was to be redefined, as in the course of time the boundary marks in many regions had disappeared and the frontier could no longer be clearly recognized. Article nine of the 1921 treaty between Afghanistan and the U.S.S.R., which envisaged a plebiscite among the former inhabitants of Panjdeh and of the border regions of the Turkmen republic (never subsequently carried out), was to be annulled. Article ten of the same treaty, which provided for the U.S.S.R. to make Afghanistan yearly payments of money as assistance during the early days of the latter country's independence, was also to be annulled (only one or two payments of this money were ever made).

Alghanistan—always a loyal member of the former League of Nations—applied for membership of the United Nations and was elected in 1946.

Agagianian, Gregorio Pietro XV

Cardinal Agagianian (1895—), Armenian prelate, was born Sept. 15, 1895, at Akhaltsikh, in Caucasian Armenia. He studied and taught at the Congregation de Propaganda Fide in Rome and was ordained in 1917. Appointed in 1921 as vice-rector of the Armenian college at Rome, he was made rector in 1925, titular bishop of Comana in 1935 and patriarch of Cilicia in Armenia in 1937. Many members of the Roman Catholic clergy in the United States had studied under the patriarch at the Propaganda Fide, and he was a classmate of Cardinal Francis J. Spellman in Rome. Patriarch Gregorio was the highest dignitary among the 32 ecclesiasts that Pope Pius XII had proclaimed cardinals at the consistory in Rome, Feb. 18, 1946.

Agricultural Research Administration

Research seldom produces results overnight. Many of the achievements of the Agricultural Research administration of the U.S. Department of Agriculture that can be credited to the decade 1937–46 had their beginnings much earlier. It was so, for example, with hybrid corn, a major development of plant breeding.

Utilization of Hybrid Vigour.—The merits of hybrid corn had been proved by 1933, and in that year one out of every 1,000 ac. of corn in the U.S. was planted to hybrid varieties. In 1937, this acreage had expanded to 8% of the total, or 7,600,000 ac. By 1946, hybrids were planted on two-thirds of the corn land of the country, occupying 60,300,000 ac. In the corn belt, 99% of the corn was grown from hybrid seed. This change from open-pollinated corn meant an increase in yields averaging 25%.

Carrying the utilization of hybrid vigour further, plant scientists developed methods of producing hybrid onions and alfalfa. Both proved to be higher yielders than their open-pollinated parents. In livestock breeding, the hybrid principle was tried with swine, cattle and poultry.

In 1939, an experiment in crossing dairy breeds was begun to find out whether hybrid vigour and increased milk production would result. Stock of high quality and sires proved for their ability to transmit high milk-producing capacity to their female progeny were used. In almost every case the crossbred heifers were better producers than their dams. A striking characteristic was their persistency in milk production. The actual increase in production was 20% more than was expected on the basis of the records of their sires and dams. This could be the result of hybrid vigour.

New Plant Varieties.—New varieties of many crop plants were developed and released to farmers and growers with the co-operation of state agricultural experiment stations. Notable improvements were made in grains. About 51 improved varieties of wheat were distributed during the decade. The total production of wheat in the U.S. was estimated to be 550,000,000 to 600,000,000 bu. higher during the war years 1942–45 because of the development and distribution of varieties resistant to the major hazards of diseases, drought and insects.

A good example of improvement in wheat was Cadet, in the group of hard red spring wheats. Released by the U.S. department of agriculture and the North Dakota Agricultural Experiment station in 1946, Cadet promised to excel older wheats in yield and in milling and baking properties. Its release followed a decade of behind-thescenes breeding and testing work, which began with crossing the Merit and Thatcher varieties. It was increased and tested at 24 agricultural experiment stations in eight states and was found to be consistently high yielding, resistant to stem and leaf rusts and early maturing.

It was partly because of the increased yield per acre of new resistant wheats and of hybrid corn that the U.S. was able to produce during World War II nearly 50% more food than in World War I with 4,000,000 fewer men on the farms.

Oats was another cereal improved by plant breeding. Improvement of oats enhanced the value of this crop as a livestock feed at a time when a substitute for wheat and barley was needed. Among the new varieties were Clinton and Benton, released in 1945 by the department and the Iowa; Illinois and Indiana experiment stations. They had the advantages of higher yields, stiffer straw and greater weight per bushel than most other varieties, besides being

¹The administration in 1946 comprised seven research agencies—the bureaus of agricultural and industrial chemistry, animal industry, dairy industry, entomology and plant quarantine, human nutrition and home economics, and plant industry, soils, and agricultural engineering and the office of experiment stations.

rust and smut resistant.

Control of Livestock Diseases and Parasites.—The end of a long road was virtually reached in 1939 when cattle-fever ticks, carriers of tick fever of cattle, were 99% eradicated in the U.S. This meant the practical elimination of a livestock disease that formerly took a toll estimated at \$40,000,000 a year. Many cattle died of the fever; survivors were poor producers whose value was greatly reduced. Research determined that the disease was carried by the cattle-fever tick, and a campaign was begun to control the disease by eradicating the insect. To eliminate the myriads of ticks in 15 southern states seemed a fantastic attempt. But the job was done through the use of dips, sprays and livestock management methods.

Internal parasites continued to present a problem in the raising of all types of livestock. Drugs for their removal were specific—a different drug for each kind of animal and each type of parasite. In 1938, a department scientist found that a single drug—phenothiazine, a coal-tar chemical—was effective against a number of parasites and could safely be given to cattle, sheep, swine, horses and even poultry. Within five years of this discovery phenothiazine was more widely used than any other drug for freeing animals of parasites. In 1943, about 3,000,000 lb. of phenothiazine were produced and used for this purpose in the U.S.

Other control programs made strides toward completion during the decade. Bovine tuberculosis reached the clean-up stage with less than one-half of 1% of the cattle in every county of the U.S. and in Puerto Rico reacting to tests with tuberculin. The last county was added to this list in 1940.

Also in 1940, as a control measure for brucellosis, or Bang's disease of cattle, vaccination of calves five to eight months old was officially adopted as a control measure. The vaccine used, known as strain 19, was developed by the department, which controlled its manufacture. A new type of vaccine for official use in the campaign for the prevention of hog cholera was patented by the bureau of animal industry in 1945.

Dairy Herd and Poultry Improvement.—The decade 1937–46 saw the growth of two projects that brought about steady improvement in their fields. These were the National Poultry Improvement plan and the annual List of Sires Proved in Dairy Herd Improvement associations.

The poultry improvement plan was developed to aid the poultry industry through improving the efficiency of production of eggs and poultry meat and reducing losses of chicks from pullorum disease. The plan was administered co-operatively by the bureau of animal industry and a state agency in each of the 47 states co-operating. Results both of scientific research and of practical experience were made available to participating hatcherymen, breeders and flock owners. The department issued a yearly directory of chickens owned by participants in the plan, giving their production and breeding records. Official terminology was established for the identification of approved breeding stock, hatching eggs and chicks. During the first ten years of its operation, the plan contributed to an increase of about 20 eggs in the average production per hen in the U.S. More than half the breeding birds in the country were included.

In 1937, the first annual list of "proved" dairy sires was published by the bureau of dairy industry. This marked the beginning of a nation-wide program to improve the production of dairy herds through breeding. Proof of a dairy bull's breeding value was obtained by

comparing the milk-production records of at least five of his daughters with those of their dams. The list included all records, good and bad, and enabled dairymen to select sires whose daughters had been consistently high in milk and butterfat production when breeding to improve their herds.

New Insecticides.—World War II had a marked influence on insecticides. First, it cut off from the U.S. many important insecticidal substances formerly imported. Next, the U.S. armed forces issued an urgent call to the bureau of entomology and plant quarantine for materials and methods to control disease-carrying and other insects in the war areas. One of the bureau's laboratories, at Orlando, Fla., tested some 8,000 materials as insecticides and 7,000 as insect repellents. It was there, in 1942, that a compound undergoing routine test proved to be more deadly to more insects than any other known, old or new. This was DDT.

Halting a typhus epidemic in Naples, Italy, by exterminating typhus-carrying lice with DDT powder was a noteworthy accomplishment during the Allied invasion of Italy. DDT was also an important factor in the war in the Pacific, especially through its effectiveness in killing malaria-carrying mosquitoes.

The many important peacetime uses of DDT were still being explored. Experiments with its use on cattle and in barns to control flies resulted in unexpectedly large increases in production of both meat and milk. Its use to control many crop pests was limited by possibility of damage to beneficial insects, especially bees, and of injury to animals and men from eating treated plants or their products.

Methods of dispersing insecticides were also greatly improved during the years 1942–46. The "aerosol bomb" was invented by scientists of the department for use in enclosed spaces, such as rooms, tents or aeroplanes. This dispenser consisted of a metal container filled with an insecticide dissolved in a liquefied gas under pressure. Freon 12, a commonly used refrigerant, was excellent for this purpose. Opening a valve with the finger released the gas, which turned to vapour as it hit the air, carrying the particles of insecticide to all parts of the enclosed space and killing all insects present. More than 16,000,000 of these bombs were distributed to the armed forces.

The aerosol principle was adapted to large-scale outdoor use on field crops. Released under a large hood from a high-pressure container, the aerosol, containing various insecticidal formulations, killed most of the insects on the plants as the apparatus was pulled through the field.

More effective insecticides and better equipment for their application made possible a broader and more effective large-scale attack on certain insect pests. Tests with DDT applied over forest areas by means of aeroplanes or ground equipment again demonstrated the effectiveness of this insecticide in the control of the gypsy moth. The new method required much less labour and covered far more territory than the methods and materials used previously. With these improvements in methods and materials, the possibility of controlling the gypsy moth appeared bright.

A "mist blower," which dispersed an insecticide in finely atomized form for treating shade and orchard trees, was as effective and much more economical than the older type using a dilute spray. Twelve gallons of spray material went as far in the mist blower as several hundred gallons in the old type. (See also Entomology.)

Regional Chemistry Laboratories.—The congress of the United States in 1938 authorized the establishment of a laboratory in each of the four major farm producing regions of the country. These laboratories were created

to develop new and wider industrial outlets for farm products. Work was under way in all of them by 1941.

The method by which penicillin production was increased in time for the life-saving drug to be available to save the lives of thousands of war wounded was perfected by scientists of the Northern laboratory, at Peoria, Ill., in 1941-42. Penicillin, discovered by Dr. Alexander Fleming in England, could not be produced there under war conditions in large enough quantities to supply even a small fraction of the need. The problem was taken by British scientists to the Northern laboratory because of the latter's outstanding collection of micro-organisms, including moulds such as that which produces penicillin. Laboratory scientists found a culture medium on which the mould produced many times larger quantities of the drug, and they also discovered improved strains of the organism. Large-scale commercial production of penicillin was made possible as the result of this work.

The U.S. navy needed a material for cleaning the engines of naval aircraft to replace hominy grits, which was needed as a food. The Northern laboratory scientists found that ground corncobs and rice hulls—both waste products—used in sandblasting equipment, made a good substitute.

At New Orleans, La., the Southern laboratory, seeking to find or maintain markets for cotton, improved the wearing quality of cotton tire cords through use of selected varieties of cotton. Light truck tires made with the improved cord, in rigid army tests, gave 250% more mileage than tires made from regular commercial cord. Southern laboratory engineers also designed a machine which cut cotton lint so it could be substituted for cotton linters in the manufacture of smokeless powder.

To establish a domestic source of root starch for industrial purposes to take the place of imported starches, department chemists conducted intensive experiments for more than ten years on the production of starch from sweet potatoes. Their success was attested by the building, in 1945, of a modern, \$7,000,000 commercial plant in Florida to manufacture starch from sweet potatoes and other root crops.

Scientists of the Eastern Regional Research laboratory at Wyndmoor, Pa., learned how to make from cull apples a bland syrup that had several commercial applications. They also developed a method for capturing the delightful flavour, or essence of fresh apple cider.

In studying the constituents of tobacco, research workers at the Eastern laboratory found that the leaves of the flue-cured type contained small quantities of a compound called rutin. It was thought that, because of its chemical composition, rutin might have therapeutic value. In co-operation with the University of Pennsylvania medical school, the laboratory showed that rutin was beneficial in treating capillary fragility, a condition frequently associated with high blood pressure. Having found a use for rutin, the investigators sought other sources that would give higher and more economical yields. Buckwheat leaves and blossoms from young plants were found to contain many times as much as tobacco. Commercial production of rutin from buckwheat was begun in 1946.

At the Western laboratory, Albany, Calif., methods of dehydrating and compressing foods for the armed forces in the field were studied in laboratory and pilot plant. Improved methods developed there were adopted by the dehydration industry. Freezing preservation of fruits and vegetables was also a major project. In connection with this study, a product named "Velva Fruit," was made from fruits too ripe for shipment. The ripe fruit could be crushed and frozen immediately and kept until it could

be made into Velva Fruit in commercial ice-cream plants or with home equipment. The final product was of ice-cream consistency, but it contained no cream—just the fruit, a little gelatin and sugar. (See CHEMURGY.)

Diet Studies.—A pamphlet entitled "Are We Well Fed?," issued in 1941, summarized the results of a study of family food consumption in the U.S. made by the bureau of home economics (renamed, in 1941, the bureau of human nutrition and home economics) and co-operating government agencies. These reports gave a comprehensive picture of the diets and spending habits of farm, village and city families of all income levels over the United States. The startling conclusion drawn from the data and reported in the pamphlet was that one-third of the families were ill-fed according to standards of adequate nutrition. Substandard diets were usually, though not always, the result of low income. Another third or more had fair diets—barely adequate nutritionally. Only a fourth had diets that could be rated good.

Sizing Children's Clothing.—Because the traditional method of sizing children's clothing by age had serious shortcomings that caused nation-wide waste in misfits and returned goods, a study of children's body measurements was undertaken in 1937 by the bureau of home economics in co-operation with the Works Progress administration and 19 colleges, universities and other institutions. Trained workers made detailed measurements of 147,088 boys and girls ranging in age from 4 to 17 years. From the data obtained, a new system was developed for sizing children's garments, based on height and weight. Many manufacturers of children's clothing and the larger pattern companies in the United States adopted the new system of sizing. (P. V. C.)

Agriculture

The decade 1937-46 was the period of the greatest growth in productivity in the history of U.S. agriculture. It was a period in which a series of eight years of favourable weather came together with a supreme effort to increase production on the part of farmers. It also marked the coming into practical use of many of the results of scientific research of the previous half century and also the widespread use of new mechanical power machinery. The outstanding fact was that this greatly increased output was accomplished without much total expansion of area; by a declining number of farm operators and labourers. The expansion, particularly during the war years, was accomplished by a shrinking farm population under severe handicaps and shortages with very little price stimulus. The age of farm workers averaged higher than ever before and a much larger part of the work was performed by women and children than in the past. The application of newer technical knowledge was more universal than in any previous crisis. The expanded research and educational agencies, such as the staffs of the agricultural extension service, the Agricultural Adjustment administration and the Soil Conservation agency provided an army for assistance and control. While a large measure of regimentation created considerable complaint at times, the general result was good for the great majority of rural people. Gross agricultural income reached new heights and was widely distributed. The farm mortgage debt was greatly reduced. The majority of agricultural people found themselves at the end of World War II with greatly expanded resources in the form of bank deposits and bonds but with somewhat depleted farm equipment and a lack

Contour plowing on a mechanized farm in Texas

of building repairs. Land values rose at a rate comparable to the boom in World War I, but the prospect of a sustained demand for farm products was an element of security, if adjustments to postwar needs could be made gradually. Congress assured farmers that prices would be maintained at near parity levels for two years after the official end of the war. This would allow two seasons for farmers to adjust their production to reduced demand.

An analysis of U.S. agriculture as an industry, based upon surveys by the United States department of agriculture, showed the composition and character of the enterprises which made up the whole. The family farm had been the typical farm unit since the continent was first colonized. The total number of farms declined from 6,448,000 in 1910 to 6,096,000 in 1940. At the same time, farm population shrank from 32,077,000 to 30,269,000 in 1940. The number in the farm labour force reached its peak of 11,600,000 about 1910, and declined to 9,162,000 in 1940. While farm population was declining slowly, the nation's total population had expanded from about 92,-000,000 in 1910 to 131,000,000 in 1940. The percentage of farm population shrank from more than one-third to less than one-fifth of the total. This decline in the number of farm people was accelerated by World War II as millions left farms to work in war industries and other millions joined the U.S. military forces. How this shrinking farm labour force could have produced a surplus for a growing population of consumers before the war could only be explained by the steadily increasing productivity per worker caused by technical and mechanical advances. Between 1930 and 1940, the census showed a gain of only 7% in total population while agricultural production gained 12%; at the same time productivity per farm worker increased 28%.

Changes in farming modified the character of the several groups making up the 6,000,000 farms. They were no longer mostly of the family-supporting type of 1900. On the contrary, the productive farms were better and others poorer. The surplus production was coming more and more from the more efficient commercial farms located in the more productive areas. The large farms on the better soils had become better able to utilize the new results of scientific research and power machinery which had produced the great increase in production during the decade

1937–46. A large proportion of the nation's farms had become too small to be efficient as surplus producers. The census returns showed some startling facts.

Of the total number of 6,097,000 farms in 1940, 1,240,000 produced less than \$750 worth of products and had no power in animals or tractors. They averaged only \$250 output per farm and only 3.2% of the total national output. The remaining 4,857,000 farms constituted the real farm productive plant. These could be divided into three groups: (1) large, 91,000 (those with more than \$10,000 worth of products) that produced 19.2% of the total national output; (2) adequate family-sized farms, 1,584,000 (producing \$1,500 to \$10,000 worth of products) that returned 41.1% of the grand total; and (3) inadequate farms, 3,182,000 which produced from \$750 to \$1,500 worth of products amounting to 28.5% of the national total.

This analysis showed that less than one-third of the farms produced more than two-thirds of the farm output. Viewed from the standpoint of national food supply, one-third of the farms were of minor importance. Many of them could be abandoned without loss to the national economy. Their value as homes, providing more or less subsistence, was another matter.

During the decade 1937–46, nonfarm employment brought extra income to these less efficient farmers and enabled some of them to enlarge their land areas and become more efficient farmers. The government aid to tenants to buy farms was a factor in this change. The greatly increased net income of agriculture as a whole tended to advance a readjustment in the way of better farms becoming larger by absorbing less efficient small units. The 91,000 large farms averaged 2,857 ac. each, the 1,584,000 adequate family farms 253 ac., while the 4,422,000 inadequate averaged only 160 ac. each. The average size of all farms in 1940 was 174 ac.

The decade 1937-46 was generally recognized as a turning point in U.S. agricultural history because of the fact that production during the war years 1941 to 1945 reached new high records. It was seen as a demonstration of the value of technological progress designed to increase farm production. As recently as 1922 alarms had been sounded on the danger of declining food production in the face of increasing population. The latter was at the rate of 15% from 1910 to 1920 but dropped to 7% in the 1930-40 dec-

ade. Agricultural exports declined from 1920 to 1940 and increased only as supplies for lend-lease and relief were provided by government purchases after 1940. A new period of agricultural surplus production was anticipated by many agricultural authorities after the relief needs had been supplied and foreign countries had restored production. The problem then to be faced would be that of aiding the lower third of the farms to produce a more adequate income. To this end the location of small industries in crowded agricultural areas was revived, so as to provide part-time, nonagricultural employment for farm people. The increase of industrialization was generally expected, although a vigorous back-to-the-land agitation was revived in some quarters, as it had been after World War I.

U.S. Crop Production.—The outstanding fact of U.S. agricultural history during the decade 1937–46 was the remarkable crop production attained. Not only was the total imposing; the breadth of the increase, spreading over the great majority of crops and livestock, was unprecedented. Only a very few crops failed to set new records during the decade, and many of the new high records were far above what most optimistic forecasters had considered possible.

Estimates of gross farm production by the United States department of agriculture placed the high record of 1944 at 18% above 1939-a gain of 3.6% a year. During the 20 years before 1939 the gain had been only 9%, or less than ½% a year. The 9% expansion between the two world wars was sufficient to meet all needs and pile up some surpluses. United States farms could have produced more had there been a demand for the product. War was the stimulant to bring out the real productive capacity of the farm plants. It is noteworthy that this greater production was made with small expansion of acreage and with a declining supply of labour and materials of production. The increase of 29% from the end of World War I to 1944 was made on only 5% more cropland. One factor was the shift of about 50,000,000 ac. from the production of horse and mule feed as mechanical power increased. The production of feed for work animals made up 22% of all farm production in 1919, 11% in 1939 and only 8% in 1944.

The shift from animal to mechanical power was the most important single factor, aside from favourable weather, in the great increase of production during the decade 1937–46. Just before 1937, the nation experienced the two most serious drought years, 1934 and 1936, in its agricultural history. In contrast, the ten years 1937–46 saw probably the longest succession of favourable seasons in U.S. history. All regions participated in the increased productions. The west north central region, the worst sufferer in 1934 and 1936, made the greatest gains, followed by the mountain and Pacific regions.

Measured as farm output (gross production less that part used for farm-produced power in the form of feed used for work animals), the increase was faster than in gross farm output. The output of the west north central states—Minnesota, Iowa, Missouri, the Dakotas, Nebraska and Kansas—increased more than 60% by 1944 over the prewar 1935–39 average. This was the area in which the machine had replaced the horse to the largest extent. Farm-produced power was only 7% of gross farm production compared with 16% in the east south central states where the horse and mule were still used to a large extent. Compared with the average of 1923–32, preceding the drought years, the 53 crops produced 111.5% in 1917, 123.9% in 1942 and about 121.2% in 1945. The gains

from 1937 to 1945 of 22 field crops were from 199.5% of the pre-drought years in 1937 to a top of 121.3% in 1942. Thirteen fruits increased from 125% to 142% in 1944, 8 vegetables for processing from 146% to 215%, and 17 market vegetables from 128% to 168.9%.

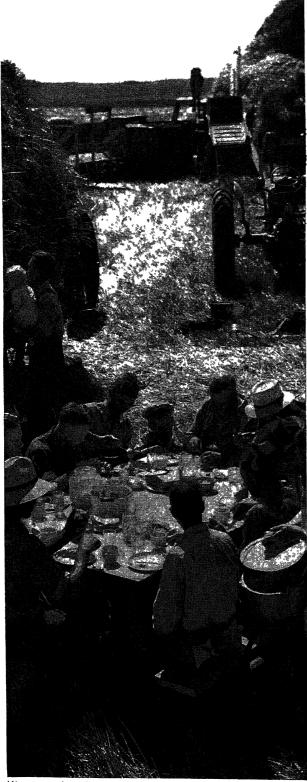

The smaller losses of crops planted but not harvested after 1937 also constituted a favourable factor. From 1937 to 1945 it ranged from 24,570,000 ac. in 1937 to only 10,058,000 ac. in 1945 and averaged 15,000,000 ac. In the preceding eight years the annual losses exceeded 42,000,000 ac. three times and averaged 25,000,000 ac. These losses were chiefly in the small grains, winter wheat and oats.

Of the 53 crops reported and estimated by the United States department of agriculture, more than 40 made high production records during the decade, and most of them during the war years 1941-45. Some of these records were due to stimulated expansion, wheat for example, but others were the result of plantings that had been made in earlier years just coming into the bearing age, as in the case of grapefruit. Of the major grain crops, the record productions of corn, wheat, oats, barley and rice were outstanding. Rye and buckwheat were conspicuous examples of subnormal yields. Potatoes and almost all vegetables made records. Tobacco and peanuts made bumper crops, and all fruits were abundant. Only cotton, of the major crops, declined to a new low in production. Hay and the newer feed crops, soybean, lespedeza and sorghum, returned new high totals.

The bountiful yields of most crops from 1937 to 1946 were the result of the favourable seasons, improved culture, better seed and the use of more machinery. The trend of the combined yield of all crops had been downward for the decade before 1937, because of the bad years 1934 and 1936, and were below the pre-drought average 1923-32. In 1937, yields were above the average of the previous two decades and continued to gain until 1945. In terms of the pre-drought base index as 100, the record was: 1937 118%, 1942 136.2% and 1945 130.2%. The greatest gains were in the west north central and mountain areas. In general, yields increased on the better lands, and the poorer lands were turned to noncrop uses. The most important high yield record made during the decade were those of cotton, 293.5 lb. per ac. in 1944; tobacco, 1,117 lb. per ac. in 1944; corn, 35.2 bu. per ac. in 1942; potatoes, 150.6 bu. per ac. in 1945 and wheat, 19.8 bu. per ac. in 1942. These national averages were less impressive than the records made by some leading states in the production of each crop.

The area of U.S. agriculture as expressed in terms of cropland was estimated at about 424,000,000 ac. during the war years, compared with 426,000,000 ac. in the prewar period. Estimates by the United States department of agriculture covering 52 crops harvested were 338,400,000 ac. in 1937, a decline to 321,700,000 ac. in 1939 followed by expansion to 350,900,000 ac. in 1944 and 346,900,000 ac. in 1945. The cultivated area on U.S. farms had changed relatively little since 1919 as a whole, although there were changes by regions. These regional shifts had taken place mostly before 1937—from 1919 to 1929. There was a decline of acreage in the New England, middle Atlantic, south Atlantic and east north central states which was offset by increases in the mountain, Pacific and west south central regions.

The changes in acreage of principal crops in the decade 1937–46 were more significant than total changes. Most striking was the decline in cotton from 33,623,000 ac. in

Minnesota wheat harvesters at lunch in the summer of 1943. U.S. farmers worked long hours during the war years to supply the unprecedented food needs of the U.S. and its allies

1917 to 17,688,000 ac. in 1945 and 18,316,000 ac. in 1946. Notable increases were rice, 1,099,000 ac. to 1,506,000 ac.; soybeans, 2,586,000 ac. to 10,873,000 ac., and peanuts, 1,538,000 ac. to 3,183,000 ac.

Wheat production was high in 1938 and continued so

until 1944, when a record crop was produced. The United States entered World War II with large stocks of wheat which reached the huge total of 632,000,000 bu. in 1942equal to many whole crops of preceding years. Food and industrial uses expanded in 1942 and 1943, bringing the total supply down gradually. By 1946, stocks were so reduced that for a few months early in that year shipments for relief purposes were short, and special price inducements were used to stimulate deliveries of wheat from farms and to move stocks held in elevators. The whole record for wheat during the decade was one of abundance, which at any other time would have been a serious surplus. The big crop of 1946 assured an ample supply for the next year notwithstanding the heavy demands for relief shipments. This huge wheat production during the war was accomplished with an average price much below the level of World War I-about \$1.50 per bu. compared with a fixed price of \$2.10 per bu. in 1917-19.

The corn crop was even more remarkable than wheat during the decade. The average of the ten crops 1937-46 was 2,863,000,000 bu. with no crop below the 2,000,000,000 total, and 5 over 3,000,000,000. Up to 1937, only two 3,000,000,000 bu. crops had been produced, and a running average of about 2,500,000,000 bu. was regarded as the maximum that could be produced aside from a few exceptional years. But these exceptional years came in 1942 and continued to the end of the decade. This abundant feed supply was largely responsible, together with good hay and pasture, in supporting the large livestock production of World War II. The large corn crops were produced on an acreage smaller than the average of the previous decade, but with record average yields. Improvement of seed corn, widespread use of hybrid seed and expanded mechanization were the causes of the increased output.

The minor grain crops—oats, barley and rice—each made large crops during the decade. Nine of the ten oat crops were over the 1,000,000,000 bu. level, and those of 1945 and 1946 were about 1,500,000,000 bu. each. Barley was less important, yet made a crop in 1942 almost one-third larger than any crop before 1937. Rice increased steadily during the decade from around 52,000,000 bu. to 70,000,000 bu., thus assuring an ample domestic supply and a surplus for export. Rye was the only grain crop that did not make new record production during the decade. The relatively new crop, sorghum, expanded rapidly and contributed largely to the feed supply. The eight principal grains increased from an average of about 110,000,000 tons in 1937 to an average of about 135,000,000 tons per year in 1945.

The tame and wild hay crops of the decade increased steadily, supplemented by a large increase in sorghum grown for forage and silage which more than doubled in output. Of the oil-bearing crops, principally soybeans, the increases were most substantial. Peanut production almost doubled, and dry beans also made new high record output. Potato output was maintained at the maximum of the previous decade and with a record yield turned out three crops of over 425,000,000 bu. Flaxseed and all of the hay and clover seed crops reached high peaks-about double the average of the decade before 1937. Tobacco was an outstanding crop through most of the decade, exceeding 2,000,000,000 lb. for the first time in 1946. Cotton was the only major crop to shrink steadily during the period, from nearly 19,000,000 bales in 1937 to a low of 9,195,000 bales in 1945, and 9,290,000 bales in 1946.

The expansion of fruits and vegetables proceeded steadily. The orange and grapefruit crops increased more than 50%, particularly the latter. Apple production suffered

two very disastrous years, 1943 and 1945, but did better than in the previous decade. The 15 principal fruits as a whole returned crops that averaged about 20% above the output of the decade before 1937. Vegetables for fresh market and processing increased about 50%.

After the very productive years 1942 to 1945, the end of major hostilities was expected to be followed by a drop in agricultural output. But the record of 1946 was on the same high scale as that of the previous five years. The wheat crop (August estimate) was 1,132,000,000 bu., an alltime high record; corn, 3,487,000,000 bu., also a record; oats, 1,498,000,000 bu., a third grain record. Other top production crops were tobacco, peanuts, soybeans, potatoes, sugar beets, peaches, pears, grapes and rice. Pastures and feed grains in addition to corn provided abundant feed for livestock of all classes. The labour problem on farms was partially solved by returning service men, but there were still shortages of machinery and supplies.

Livestock Production.—In the decade 1937-46, U.S. livestock production reached a peak in 1944 and then declined. The cycle of livestock expansion and decline coincided with the good years for pastures, hay and grains, with the result that the output of meats was at a high level at the time of greatest need during World War II. The numbers of cattle, milk cows, hogs and poultry all increased after 1937 until 1944. Sheep numbers increased until 1942, then began to decline. Horses and mules continued the decline that began with the introduction of the tractor and reached new low numbers, about half the number on farms in 1918. The pig crop increased with the growing supply of corn and with the strong war demand, from about 61,000,-000 head in 1937 to the record of 121,696,000 head in 1943. Per capita meat production averaged 125 lb. in the prewar period 1935-39 and rose to 177 lb. in 1944. While meat production as a whole increased more than 40% during the war, military and lend-lease demands were so large that the civilian supply increased only 20%. High consumer purchasing power absorbed the increased production so rapidly as to create shortages in some localities. The meat demand exceeded the greatly enlarged supply.

Dairy production started a cycle of increase in 1937, after the drought years 1934 and 1936. The number of cows increased steadily to 1945. Large crops of feed grains, hay and lush pastures favoured milk production, which was increased further by better feeding and care. Milk production grew steadily, from about 103,000,000,000 lb. in 1937 to the record of more than 123,066,000,000 lb. in 1945. Butter production declined over 30% during the decade because of the strong demand for fluid milk and the diversion of milk from butter to cheese by the government. Per capita butter consumption declined from 16 lb. in 1937 to an average of only 11 lb. in 1945. Severe rationing did not save enough butter to meet the war needs. While the government reserved 30% of all the butter produced in 1943-44, civilian stocks shrank seriously, causing the government to cease buying for several months in late 1943 and early 1944. Cheese production was increased to supply military and lend-lease requirements, the output about doubling in the decade.

Poultry raising responded to the war need quickly and grew from a low level in 1937 to the record production year 1943, when 934,000,000 birds were raised. Egg production followed a similar line and advanced year by year from 37,564,000,000 in 1937 to the peak of 57,874,000,000 in 1944. This record was followed by a slight decline in 1945–46. The rate of production per hen rose from an average of 130 eggs per year in 1937 to 152 eggs in 1945. Outstanding changes in the poultry industry were the

growth of the specialized broiler business and better breeding and feeding of laying flocks. Turkey raising grew steadily after 1937 and provided about 4.6 lb. per capita compared with 25.3 lb. of chicken meat. Turkey raising became a large-scale specialized business, with the average of commercial flocks numbering thousands of birds. Egg consumption by civilians increased from 306 eggs per capita in 1937 to about 390 eggs in 1946. The military and lendlease demand was large, the egg-drying industry using the large part of the output for shipment overseas.

Of agriculture's production food remained the largest part, although the production of fibres, oils, etc., used in industry rose to about a third of the total. Feeds turned into meats, dairy products, eggs, etc., cannot be measured as food. Estimates by the United States department of agriculture gave the food production of the base period 1935-39 as 100. For that period, 93.7% of U.S. national food supply was produced within the country and 6.4% was imported. Domestic production increased steadily to 125% by 1942, 138% by 1944 and 136% by 1946. Imports continued to be about 6.5% through the decade. The increase in the volume of food production during the 6 years 1939-46 was almost as large as the increase for the 30 years from 1909 to 1939.

The distribution of the national food supply in the prewar period was 97.4% to consumers and 2.6% for exports; net imports were about 4%. By 1941, the military and lend-lease needs began to take 2.4% and 2.6% respectively. The military takings increased to 8.1% in 1942, 15.2% in 1943, 17.4% in 1944 and 17.1% in 1945, after which they dropped to 3.7% in 1946. Lend-lease takings increased to 6.5% in 1942, 9.3% in 1943 and 8.8% in 1944. The 6.8% taken in 1945 and 7.8% in 1946 was chiefly for relief. At no time were the shipments for lend-lease as large as the military requirements except in the case of some particular foods at certain periods. Government stocks were being built up in 1942 and 1943. By late 1945 these military and government stocks were released as the forces were demobilized, and civilian supplies were increased.

Total food supplies were about 38% above prewar, and even with the large amounts going to the military forces, etc., civilians increased their rate of food consumption. Estimated per capita food consumption, with 100 equal to the prewar base, was 104 in 1941 and 1942, 105 in 1943, 109 in 1944 and 110 in 1945. Full employment at high wages led the workers to demand the best food available in as large amounts as rationing would permit. Total food production was not equal to the full demand. It was estimated that 7% to 10% more would have been needed to meet total demands. In other words, rationing probably saved that amount. The years of greatest shortage were the years of the highest United States production, mid-1944 to mid-1945, the final effort of the war in Europe.

The supply of meat was sufficient to enable civilian consumers to increase the average per capita consumption of meat from 125 lb. in 1935–39 to 149 lb. in 1944. The principal increase was in pork, from an average of 56 lb. in 1935–39 to 76 lb. in 1944. Beef consumption increased from a prewar average of 54 lb. to 61 lb. in 1942 and then dropped to 54 lb. in 1945. The demand for meat was so strong in 1944 that consumption might have reached 170 lb. had supplies been available. Meats became scarce early in 1945 because military requirements took 20% of the total supply and production of pork was declining.

Per capita consumption was estimated at 137.7 lb. compared with 125.6 lb. average 1935-39. Consumption in

1946 was estimated in September by the United States department of agriculture at about 143 lb. per capita. Meat production during the first half of 1946 was about the same as in the first half of 1945. Exports were increased in the spring and civilian supplies became scarce in May and June when livestock was held on farms in view of the possible end of price control. The lapse of price controls in July led to large marketings. When price ceilings were restored, heavy marketing ceased and supplies became very scarce. Meat production in September was the lowest in years; with final removal of price controls in October, however, supplies again became plentiful. The number of cattle on feed in the corn belt was $45^{\circ\prime}_{10}$ below the number a year earlier on Aug. 1. Prices of all meat animals reached record high levels during the non-price-control period in July and August, and again after Oct. 1946.

Agricultural Policies and Controls.-The Agricultural Adjustment administration in 1937 was operating on a program of agricultural conservation rather than one of production control. Goals were set up for soil-depleting crops for states, counties and farms. In the case of some crops, referenda of growers were held to determine whether a majority of growers desired to participate in the plan. Maximum payments were calculated for each farm. Full payment was made only if the soil-depleting acreage did not exceed the goal and if there was sufficient acreage of soil-conserving crops. The national goal of 305,000,000 ac. of soil-depleting crops was divided into county and farm goals by state and county committees. For 1938 this goal was reduced to a national total of about 275,000,000 ac., reflecting the fear that large production would result in burdensome surpluses. The objective of the farm program after 1932 was to restrict production and thereby raise prices of farm products. While the policy had changed to that of conservation, stimulated by payments to farmers, the idea of restricting total production of some crops was a secondary object in 1937 and 1938. The need for increasing production for war purposes had not yet been recognized; the threat of war was not evident to most Americans in 1938. Even at the end of 1939 the probable effects of the war in Europe were not realized. The secretary of agriculture, in his report for 1939, said: "It would, of course, be folly to regard the new war as in any way a solution of our farm problem" and urged that the plans of 1937 and 1938 be continued. As subsequent developments showed, the war almost completely changed the situation. Restrictions on production gave way to stimulation; soil conservation was continued to some extent, but fertility was expended rapidly by the heavy cropping. Price controls were shifted to a policy of holding prices in check rather than raising them.

The organization that had been developed to control agriculture was quickly turned into an agency to stimulate production as soon as the need became evident in 1940. By 1940, each of the 3,022 agricultural counties in the United States had an AAA committee. About 135,000 farmers were enlisted as county committeemen to be local leaders in operating government agricultural campaigns. About 6,000,000 farmers were co-operating in some manner, and AAA was practically universal.

Government payments to farmers were about \$367,000,000 in 1937, increasing to \$482,000,000 in 1938 and to \$807,000,000 in 1939. The total cost of the AAA program in 1940 was reported as \$908,000,000, divided as follows: soil conservation, \$518,000,000; parity payments, \$215,000,000; purchases of agricultural commodities by the govern-

ment, \$67,000,000; Sugar act payments, \$47,000,000; expenses of administration, \$61,000,000. The division of these payments was: to cotton growers, \$215,000,000; corn, \$150,000,000; wheat, \$138,000,000; sugar, \$47,000,000; other crops, \$20,000,000; ranges, \$14,000,000 and general, \$172,000,000. Government payments direct to farmers were reported for 1941 to 1945 as follows: 1941, \$586,000,000; 1942, \$691,000,000; 1943, \$672,000,000; 1944, \$804,000,000 and 1945, \$750,000,000.

By the end of 1940 the "National Defense" campaign had begun, but the government was not yet aroused to the prospect of war. It was not expected that United States production would have to be increased materially. The alarm was over the loss of U.S. export trade. It was believed that the loss of this trade and the surpluses on hand would meet all requirements. The idea was still held that, because of the loss of the foreign markets and the large stocks, production restriction should be continued. The "ever-normal-granary" program which had come into full operation in 1939 was pointed out as a useful defense measure.

The farm markets were unsettled through 1939 and 1940. Sugar was at a premium, but the government authorities did not anticipate a shortage because the United States and its possessions produced 80% of domestic requirements. The loss of the Philippines was not foreseen. General farm markets were weak through 1938–39 and into 1940. Grain exchanges pegged prices at the request of the government in mid-1940. Yet at the end of 1940 the idea was held by the secretary of agriculture that farmers should be aided to get more nonfarm income. The shadow of surpluses was still depressing prices.

The value of the AAA program to agriculture was the subject of vigorous debate in 1937-39. Prices had risen after 1932 and net income to farmers had advanced, but prices began to decline in 1937 and continued lower in 1938, 1939 and 1940. Some prices dropped back almost to the low level of 1932. The cash payments were of direct assistance to farmers, but the fact that the money came from taxation led many farmers to feel that they were only paying themselves and that the need was for better markets abroad. The fear that the payment system must come to an end some time led to constant speculation as to the future of AAA. The efforts of the government to broaden the consumption markets by distributing food under the stamp plan to the small-income families was not generally approved except as a relief measure. The war came just in time to check a growing conflict over agricultural policy and to provide a new activity for the thousands of government agents. The several agencies that had been set up to handle farm products owned by the government were available to turn into war emergency agencies. Such a case was that of the Surplus Marketing administration, which was changed into a purchasing agency to collect food for Great Britain.

Agricultural policy changed rapidly in 1941. An increase of about 7% in 1942 was called for by the government for the aid of Britain, and other countries to be aided by lend-lease. The complete about-face, however, did not come until 1942, after Pearl Harbor. The war began for the United States in the early winter, which gave ample time to plan new crop production for 1942. The fact that production jumped suddenly to a new high in 1942 was not so much the result of planning as of favourable weather. While lend-lease exports took about 8% of crop production, the increased yield of 15% more than offset it. The immediate need for supplies for the United States military forces had not become large in 1942 but could be

foreseen for coming years. The general agricultural policy after 1942 continued to be the retention of soil conservation as much as possible while stimulating production where needed and maintaining adequate reserves. By 1944 the administration began to look ahead to the postwar period when the main objective might again be the reduction of production in some lines and the control of surpluses until the world again attained a balance between food production and demand.

Relief needs were larger than expected in 1945 and 1946 and drained off the surpluses that had caused farmers to fear a price decline when peace came. The needs of U.N.R.R.A. were greater than the funds available. The United Nations planned to take over part of the work of relief from U.N.R.R.A. while the rest was turned over to private organizations. The Food and Agriculture organization proposed a World Food board to balance world-wide production, but this scheme was opposed by Britain, who had been one of the chief financial supporters of U.N.R.R.A., and was referred to a commission for further study.

Farm Prices.—At the beginning of the decade 1937–46, farm prices were recovering from the very low level of the five previous years, when the index of farm prices was down to 65 compared with the 1909–14 level of 100. Prices had risen to 121 in 1937 but dropped to 93 in 1939 and then began to advance. The increase in-prices of all farm products was most rapid in 1941, 1942 and 1943, when they advanced from the average of 100 for 1940-to 192 for

Mexican migratory labourers pruning a cantaloupe patch in the Imperial valley, Calif., before World War II. During the critical labour shortage lasting throughout the war, great numbers of migratory workers were absorbed into war industries

1943. This rise was followed by a levelling off in 1943 and 1944, caused by the very large production of those years, then by another rise to 201 in 1945 and to 264 by Dec. 1946. There were wide variations in the price changes of different groups of crops and livestock during the decade. The most striking advances were those in tobacco, cotton, oil-bearing crops, fruit and truck. Tobacco was at 204 in 1937 and 365 in mid-1946. Cotton advanced from an index of 90 in 1937 to 194 in 1946. These annual averages omitted the temporary variations that made records for some crops from time to time. Price ceilings also tended to hold the increases to gradual changes. Prices paid by farmers during the decade followed a somewhat different curve, beginning at a higher level in 1937, which was followed by a slight decline and then a slower rise until 1946. The index of prices paid by farmers for commodities, interest and taxes was at 134 in 1937, declined to 125 in 1939 and then rose constantly to 181 in April 1946. Farm wages advanced much more rapidly, from 126 in 1937 to 362 in April 1946. At the same time the wage earnings of factory workers, which were at 299 in 1937, advanced to an average of 475 in 1945.

The parity ratio (relation of prices received to prices paid by farmers) was at 91 in 1937 and declined to 76 in the two years 1938 and 1939, followed by a steady advance to an average of 116 for 1945 and the first half of 1946. For the period 1921 to 1941, farm prices had been below parity. The parity index rose more rapidly because prices paid by farmers did not advance so rapidly. The OPA's declared policy of holding farm or food prices and wages

from rising was not carried out. If prices of cotton, wool and feed crops were taken out, the food crop index rose at about the same rate as earnings of factory workers until 1943. A comparison of prices during World War I and II showed that prices advanced more rapidly and to much higher peaks in World War I. This followed the trend of all prices, which rose to greater heights by 1918 than they had by 1944. Farm prices in World War II began to rise before the rise in prices of nonfarm products because of the fact that the control of prices was first imposed on nonfarm products. Parity did not reach the level of 1915-19 until 1943, however. The increased income of agriculture in World War II was not due so much to a better price relationship as to the greatly increased volume of production. From 1914 to 1918, all farm production had increased only 5%, but in the corresponding period of World War II it was 22% larger. Crop production actually declined from 1914 to 1918, but gained slowly in the first years of World War II, while livestock output gained much more rapidly in the first years of World War II. The main factor in the gains of crop production in the latter part of the decade 1937-46 was the several years of favourable weather.

Price control began in 1942 with the passage of the Emergency Price Control-act. A price administration was set up in April 1941 as well as a labour board, but without conspicuous results. The law providing for loans on certain "basic" crops at 85% of parity was passed in May 1941. The Steagall amendment providing for support prices on nonbasic crops was passed in July the same year. Under this amendment the secretary of agriculture, and later the War Food administration, was authorized to announce price supports for any products needed for the war effort at any level thought necessary to secure adequate production. This authority was in some respects in conflict with that of the price administration. Numerous conflicts arose which resulted in confusion and misunderstanding both among the officials in charge and the general public. Some orders caused prices of feeds, such as corn, to get out of line with prices of hogs and brought about results contrary to the intended purpose. The divided authority with respect to agriculture became a serious administration problem in 1943 and continued even after the discontinuance of price control in 1946.

The "roll back" order was issued in early 1943 to "hold the line" against inflation. This meant that the prices of meat and butter would be reduced to the level of Sept. 1942 and that subsidies would be paid to processors so that the price reductions would not be passed back to farmers. The Reconstruction Finance corporation paid the subsidies to the processors. In 1943 the secretary of agriculture announced "incentive payments" for several crops to assure production up to a certain goal. These subsidies were made for each farm for output between 90% and 110% of the goal for that farm. The Commodity Credit corporation was authorized to handle certain of the subsidies.

Vigorous opposition to subsidies arose among organized farmers and trade groups, and started a struggle in congress in 1944 that lasted through 1946. The question arose of revising the "parity" concept to bring about a fair relationship between the producer and consumer. The idea of developing a "parity income," rather than market price, received much attention. The Steagall amendment extended the protection of agriculture two years after the declared end of the war. In the meantime, farm prices

were above 100% of parity after 1944 up to 116 in 1946, yet the markets of several farm products were fluctuating widely and farmers were in doubt as to their future plans. Many producers remembered the price break that followed World War I and were planning accordingly, which to some extent accounted for farmers' general conservatism in 1945–46.

A vigorous struggle developed in congress in the spring of 1946 over the renewal of the Price Control act. An interim period was created by the presidential veto of the first bill passed by congress. Prices rose and declined irregularly for several weeks until the second bill was passed and approved. The new Decontrol board found it impossible to restore the controls as they had been, and by Oct. 23, 1946, price controls had been lifted from all foods except rice, sugar, syrup and molasses.

Marketing Costs.—The higher prices of foods and the large total increase in the value of U.S. agricultural production tended to obscure the increase in marketing costs. The consuming public was likely to overlook the cost of distribution represented in the prices paid at the retail store. Measured in the part of the consumer's dollar passed back to the producer, the relationship changed slowly in the producer's favour after the United States entered World War II. The 1935-39 average farmer's share of 40% continued through 1940. In 1941 the increase began and the share was 44%, advancing slowly to 54% in 1945 and to 55% in the early part of 1946. A downward trend to 52% occurred in late 1946 which was attributed to the advance in retail prices and the decline of farm prices. The marketing charges as percentage of retail cost were estimated at 59% average 1935-39; they rose to 60% in 1940, then declined to 50% in 1946.

The national marketing bill for farm products exceeded the amount received by producers for the same products. The importance of this item in the national economy was shown by the fact that in 1939 the food marketing bill amounted to 13% of the national labour income. The business furnished full-time employment for about 4,000,-000 persons. The average cost of marketing farm food products was estimated at an average of \$8,400,000,000 in 1935-39. The total increased slightly to \$8,600,000,000 in 1940 and to \$9,200,000,000 in 1941, then rose to almost \$11,000,000,000 in 1944. Government marketing subsidies covered about 6.5% of the charges in 1944 or \$700,000,000, and with these deducted the total marketing bills showed only a slight advance between 1942 and 1944. Estimates for the years before the decade 1937-46 showed very little change between 1919 and 1939. The increase in volume was offset by the reduction in marketing costs. These marketing costs did not fluctuate as widely as the farm prices or retail value of food products. These estimates cover the changes between the farm and the sale in the retail store and do not represent the cost of services in public or private eating places. The total cost of food to the consumer covers charges for services that changed considerably during World War II, when a larger proportion of consumers ate outside the home. This change is shown by a comparison of the retail value of farm food products and total food purchases by consumers. The latter includes such items as coffee, tea, cocoa and spices which are not products of U.S. agriculture. The 1937 estimate of retail food value compared with total consumer expenditures was as 14.6 to 16.2. By 1944 this relationship was as 21.7 to 30.4. This meant that the consumer was paying a much higher charge for labour in retail food preparation.

Marketing different groups of foods varied in the extent of increases. Meat showed the smallest change and fruits and vegetables the greatest. During the period 1929–40 the cost of labour was estimated to be 45% of the marketing bill. The relationship of the cost of food to total income was of interest in showing the part that agricultural production played in the national economy. The estimated total income per person in the United States averaged \$521 in 1935–39. The expenditures for food per person was estimated at \$118, or 23% of the income. For 1944 the total per capita income was \$1,134 and the outlay for food \$241, or 21% of income. Food cost consumers relatively less during the war years than during the prewar period.

Farm products, particularly high-quality fresh fruits and vegetables, were shipped experimentally by air in 1943-46. These tests indicated that air-borne products would have to sell at a premium for some time to cover the higher cost. In 1946 the competition of new air-freight lines, however, resulted in some rate reductions which promised to stimulate more rapid developments. The great improvements in cargo planes during the decade made forecasts hazardous. It did seem likely that air-transport of certain products such as flowers, the more delicate sub-tropical fruits, and other products which might sell at a premium for high quality would move by air in the near future. The Florida fruit areas were three days away from New York and Chicago by rail but only eight hours or overnight by air. Seasonal production required that other cargos be found in order to employ planes continuously.

World War II placed a great strain on U.S. transportation facilities, and railroad equipment suffered a constant lack of replacements. The quantity of locomotives and cars was constantly short of needs and had not been relieved by the war's end. On the whole, the various transportation facilities did a splendid war job for agriculture, and there were relatively small losses from lack of transportation. Shortages of freight cars led to some considerable losses of grain during the harvest season in the wheat belt, and this shipping was tight through 1946. While the number of freight cars ceased to decline in 1944 the number was inadequate and the losses of old refrigerator cars were serious. Numbers of heavy trucks were increased with the end of the war, but heavy demands for exports continued.

The decision of the Interstate Commerce commission in 1945 reducing class freight rates in the south and west had little effect on agriculture since most farm products continued to move on commodity rates rather than class rates. The decision represented a tendency for more national uniformity in rates, however, which would ultimately benefit farmers.

Price policies were the subject of continual controversy during the whole decade 1937-46. The Agricultural Adjustment administration began with the purpose of raising farm prices by limiting production to market requirements and by cash payments to increase the farmer's income in relation to the cost of the things he had to buy. This policy was opposed by many persons who contended that reducing production did not necessarily raise prices, since a large crop at low prices brought about as much money as a small crop at high prices. Others argued that the parity relation was not fair to producers, since they did not buy the same things that they did in the base period 1909-14. Still others, notably cotton growers, said that high prices turned U.S. foreign markets to foreign producers and resulted in domestic surpluses which would ultimately break the market. The Surplus Marketing administration bought large quantities of farm products for distribution to low-income consumers.

When subsidies were introduced during World War II to secure larger production without raising prices to consumers, the farmers objected on the ground that such subsidies would be a temporary war measure and when removed would break the markets. When the extension of OPA became the subject of a fight in congress in June 1946, the argument over price policies raged even more fiercely. During the interval in July 1946 when OPA was not in force, the price changes were explained by both sides of the controversy as proof supporting their contentions. As some prices rose and then fell quickly the opponents of government control said that free competition would prevent excessive rises. The same situation occurred after the final abolition of price controls (except on sugar, rice, syrup and molasses) in Oct. 1946.

Farm Income.—Both gross and net income of U.S. agriculture rose to new record heights in the war years 1942-46 from a level 1937-41 near the average of the previous two decades. Farming was more prosperous in the years 1937 to 1941 than it had been since 1930 but less prosperous than in the period 1924 to 1930. The boom of World War I lasted only four years and was followed by the great decline of 1921. Stated in terms of money value, the gross income of 1937 to 1941 inclusive averaged \$11,300,-000,000 while that of 1942-46 was about \$22,300,000,000, an increase of \$11,000,000,000. The high record of 1945, \$24,584,000,000, compared with the previous record of \$17,710,000,000 in 1919. This gross income included the amount of cash sales, value of products consumed on the farm, and rental value of buildings. It therefore provided a fair comparison with the gross income of other industries of the nation. In simple terms, it could be said that agricultural output doubled during the decade 1937-46. Government payments which began in 1933 added only a little to the total, about \$367,000,000 in 1937, \$807,000,-000 in 1939 and \$750,000,000 in 1945. These payments were much more important in 1937-39, when total income was lower than in the war years after both production and prices had risen.

From a fairly prosperous condition of agriculture in 1929, the decline brought gross income down to the low point of 1932, when the total of \$6,406,000,000 was less than it had been in 1910—\$7,352,000,000. The farm depression of 1932 was much worse than generally recognized because of the loss of reserves accumulated from 15 years of fairly prosperous conditions. Farmers' net income in 1932 was down to only about three-fifths of the worst year since 1910. Recovery from this very low state had proceeded slowly up to 1937, when there was a slight recession during 1938, 1939 and 1940.

Net income, a more accurate measure of the condition of agriculture, made great increases after 1941. While expenses of production increased, the big yields and higher prices were more important and increased the net return. In 1937, expenses were \$6,126,000,000 compared with net income of \$5,139,000,000. In 1942, expenses and income were nearly the same, but in 1945 the net was approximately \$13,229,000,000 and expenses only \$11,355,000,000. The most prosperous years for U.S. farmers were 1943 and 1944. Expenses of production included wages, rent, interest, taxes and other operating expenses. The latter was the largest item, amounting to more than half the total expenses and including costs of feed, livestock, fertilizer, machinery and fuel purchased and maintenance of buildings and machinery. Hired labour was second and rent of land third; all other items were less than labour

and rent. For example, in 1940, a typical year in the first half of the decade 1937-46, production expenses were as follows: operating expenses, S2,985,000,000; hired labour, \$1,000,000,000; maintenance of buildings and machinery, \$1,095,000,000; taxes, \$446,000,000; interest on debts, \$295,000,000; rent of land, \$363,000,000. By 1944, the operating expenses had increased to \$5,284,000,000; the hired labour bill doubled to \$2,094,000,000; maintenance increased less to \$1,624,000,000 while taxes were about the same; interest was less and rents were up to \$1,100,000,000 because of the additional land rented by farmers who were expanding their operations. The hired labour bill represented the greatest single increase during the period from 1940 to 1944. The latter did not fully represent the increase in labour, because much of the family labour expended during the war was not paid for in cash.

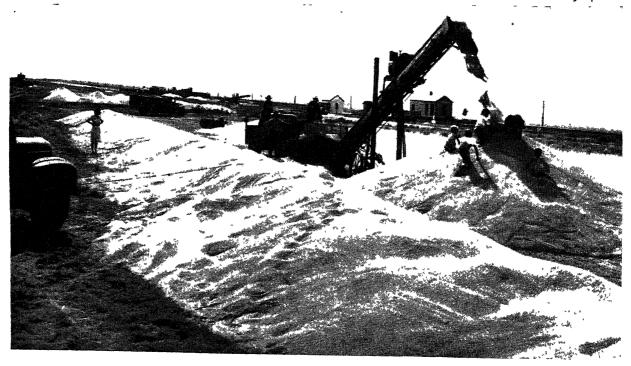

The foregoing totals for all agriculture represented the situation in the industry as a whole but did not show the returns to farms or to individual workers. When the grand total net income was divided by the number of farms, the comparison was \$898 per farm in 1940 with \$2,478 per farm in 1944. The income per capita for the total of about 10,500,000 farm workers for the same years was \$537 in 1940 and \$1,461 in 1944. An estimate of the income per industrial worker for the same years was \$1,279 for 1940 and \$2,326 in 1944. The significance of this increase is best shown by the relation to the base period 1910-14. The income of farm workers was only 145% of the base in 1940, while that of industrial workers was at 219% of the base. By 1944, farmers' incomes had risen to 394% and industrial workers to 399%. The war brought this average income of farm workers in 1944 up to the level of the industrial worker in 1941, but the latter moved ahead to a new high level in 1944. During this same period the farm population had declined from 23% to only 18.6% of total population and the number of farm workers from 10,585,000 to 10,037,000, a loss of more than 500,000 in four years. Estimates for 1945 and 1946 were not expected to show much change except in an increase in the number of workers on farms as the military forces were reduced. Industrial wages in the meantime were increasing. (For the distribution of farm income among different classes of farms and farmers, see the analysis of U.S. agriculture in the introduction to this article.)

The nonagricultural income of farmers had a bearing on U.S. national agricultural production because it tended to maintain the farm population. The amount of nonfarm income was very difficult to estimate, particularly during the war years. The United States department of agriculture estimated the wages and other income to be \$2,100,000,000 average in 1935–39 and \$3,200,000,000 in 1942. This was estimated to be offset by an average of about \$1,140,000,000 paid to city people who worked on farms in 1935–39 and \$1,771,000,000 in 1942. The difference left the net income to farm people at an average of about \$1,000,000,000.

Land Values.—The agricultural industry as represented by real estate values increased nearly 50% during the decade 1937–46. The value of farm land and buildings was put at \$34,757,000,000 in 1937 and \$56,584,000,000 in 1946. The total of all farm property, including machinery, crops and livestock was estimated by the United States department of agriculture at \$42,708,000,000 in 1937 and \$73,140,000,000 in 1946. This gain was due to both higher prices and increased volumes of production. The financial assets of farmers in the form of deposits and currency increased from \$4,030,000,000 in 1940 to \$11,600,000,000 in 1945. Savings bonds increased from \$247,000,000 in 1940 to \$3,910,000,000 in 1945.

Land values began to rise in 1941 after having been fairly stable from 1937 to 1940. The rise was at about the same rate as in World War I and by 1945 had reached 52% above the 1935-39 level. The sharpest rise came after World War I was over, in 1920, when the increase was 70% above what it had been at the beginning of the

During the bumper U.S. wheat crops of 1946, many farmers dumped overflow grain in open fields because of lack of storage space

war. The "land boom" had features similar in the two postwar periods, viz., about half the sales were for cash; about two-thirds of the purchases were by farmers; reselling took place after a brief ownership, the resales making up about one-fifth of the sales; there was an increase in the financing by individuals and commercial banks in contrast to government lending agencies. Buyers were being warned in 1944–46 that prices of land were, in many cases, beyond levels likely to be maintained by long-term farm earnings. Returning soldiers were being warned against buying at the inflated prices. In the vicinity of large cities, sales to city buyers were increasing as the fear of inflation increased.

Mortgages and Credit.-The U.S. farm mortgage debt was reduced from \$7,153,000,000 in 1937 to \$5,270,000,000 in 1945, which was a little more than half of what it was in 1929. Non-real estate debts increased about 6% from 1940 to 1945. These included a variety of loans that had not been made prior to 1937. The Commodity Credit corporation began making loans to farmers in 1934 and by 1937 had put out \$204,500,000, which grew to a total of \$352,328,000 by 1945. In addition the CCC made loans up to \$49,000,000 to co-operative associations. The latter loans declined rapidly during the war years. The Rural Electrification administration, beginning in 1936, made most of its loans to co-operative associations. By 1945 these amounted to \$345,000,000 and other loans by the same agency to over \$15,000,000. The Farm Security administration began in 1935, and its loan business had grown to \$390,000,000 by 1943. Other agencies supervised by the Farm Credit administration were increasing or maintaining their loaning from 1937 to 1946, although a part of the total could not be considered as loans to farmers since they were made for the purpose of market control, price control and other war measures.

The interest rate on farm mortgages averaged 4.9% in 1937, then was reduced to 4.5% which continued through 1941 to 1946. The total of this interest bill declined from \$341,000,000 in 1937 to \$248,000,000 in 1945 as mortgages were paid. Federal land bank rates were reduced from July 1, 1935, to July 1, 1944, to 3.5% compared to the farm loan association rate of 4%. Total non-real estate loans to farmers were reported by the United States department of agriculture at \$1,488,750,000 in Dec. 1937 and \$2,432,290,000 in June 1945.

The farm credit situation became confused by the fact that several different agencies were working in the same field. These included the land banks, federal and joint stock, the several divisions of the Farm Credit administration, the Farm Security administration, the Commodity Credit corporation and several other agencies, together with the private lending agencies of each community. Legislation was proposed by farm organizations to consolidate and clarify the work of these several agencies. These bills were the subject of much discussion in 1945 and 1946 without action by congress except for one act that gave the Farm Security administration loaning activities. There was need for new credit facilities to provide (1) technical advice to farm borrowers on the use of loans, (2) more loans for farm enlargement and adjustment to meet the new need for practical machinery-size units; (3) improved loans for veteran farmers suited to their needs; and (4) loans for farm woodlands, comprising about 20% of the forests of the country. While most of these needs were being met partially by existing agencies, the authority in the laws was not clear enough to assure positive action.

The trend of U.S. agriculture's division into two parts, the family-farm and the purely commercial enterprise,

brought up the idea that government policy should recognize these two classes and provide for them according to their national importance. Since the government was subsidizing agricultural research, education, soil conservation, etc., it was urged that those who were subsidized with loans from the federal government should be guided, or "serviced" with technical instruction to prevent waste of the loaned money. A beginning in this direction was made by the Farm Security administration, in its advice to borrowers and its requirement that definite plans be submitted on the use of the loans. It was also argued that government lending to agriculture under supervision was more desirable than the mere appropriation of large sums for farm relief in years of drought, flood or low prices. About 1,000,000 farms were estimated to be in need of readjustment quickly if they were not to drop into the lower class of unprofitable farms.

As noted above, war veterans were warned to guard against the purchase of farms at prices above their long-time earning power. The provisions for aid under the veterans relief bill stimulated considerable buying of land, but this factor was not considered the cause of the rise in land prices as much as were the purchases by farmers seeking to enlarge their holdings so as to use machinery to better advantage. The lending agencies were using caution to avoid starting new farmers with the handicap of over-capitalization.

Following World War I the farm mortgage debt per acre was at the highest point in history, 261% of the 1910–14 base. In sharp contrast, it was only 113% in 1945. Both interest and taxes were much lower in 1945. Farm real estate taxes reached a high peak in 1929, 281% of the 1910–14 base, and declined to a level of about 182% from 1934 to 1944. Agriculture was considered to be in a sound financial position, able to resist any depression of farm prices that might come during the succeeding decade. The amount of non-real estate loans held by credit agencies and commercial banks exceeded \$3,800,000,000 in 1921 but was only about \$2,400,000,000 in 1945, which was another indication of the more stable financial condition of agriculture.

The Commodity Credit corporation activities represented the largest operation during the decade. Its work began in 1933 with cotton and corn loans, followed in a year or two by loans on naval stores and tobacco. Its field was broadened in 1937 and got into full operation by 1940. During the whole period from its organization in 1933 to Dec. 1944 the total of loans made amounted to \$4,457,688,000. The largest items were cotton, \$1,954,958,000; wheat, \$1,588,824,000; and corn, \$674,369,000.

Payments under agricultural adjustment, conservation and parity programs from 1937 to 1946 constituted a large volume of financial aid to agriculture. The total for 1937 was \$308,193,000, consisting of \$68,742,000 for cotton adjustment, \$2,763,000 for rice, \$11,471,000 for tobacco, \$3,629,000 for sugar, \$871,000 for peanuts and the remainder for general conservation. The cotton program increased to \$265,595,000 in 1938 and then declined each year to \$74,204,000 in 1943. The wheat program increased from \$50,126,000 in 1938 to \$140,449,000 in 1943. The corn-hogs cost averaged about \$150,000,000 per year after 1938. Soil building was the principal conservation activity after 1939, costing about \$140,000,000 annually. The total expenditures for all programs were: \$567,645,000 in 1938; \$709,053,000 in 1939; \$639,472,000 in 1940; \$653,-362,000 in 1941; \$588,054,000 in 1942; \$598,788,000 in

1943; \$804,250,000 in 1944 and about \$711,000,000 in 1945. The sugar beet program under the Sugar act of 1937 involved payments to producers of about \$20,000,000 annually from 1937 to 1946. The cane sugar program cost an average of about \$5,000,000 per year for the continental United States and \$24,000,000 for Hawaii, Puerto Rico and Virgin Islands.

Farm Population.—The total farm population in the United States declined steadily through 1945, to the smallest number since the Civil War. On Jan. 1, 1945, the total was estimated by the United States department of agriculture and census bureau, acting jointly, at 25,190,000 persons. By Jan. 1, 1946, the number had increased to 25,990,000-the first increase after 1932. The actual numbers of persons on farms had increased until 1910 but at a slower rate than total population. In 1910 United States population was 91,900,000 of which 32,000,000 or about one-third, was on farms. The numbers on farms then declined until the depression of 1929, when a back-to-thefarm movement brought the total back to 32,000,000 by 1933 compared to a national population of 125,200,000. The declining trend was then resumed in 1934 and continued until Jan. 1944. The end of World War II marked a renewal of the back-to-the-land movement that had followed World War I for a few years. The increasing efficiency and introduction of new machinery in agriculture enabled practically the same number of farmers to feed the increasing national population.

A large part of the increase in population of the United States in cities had come from farms. The farm population increased in the decade 1937-46 by an average of about 380,000 persons because of the gain of births over deaths. At the same time thousands moved to and from cities, the net result being a loss to the farm group every year of the decade. This loss by removals from farms averaged about 550,000 from 1937 to 1940. With the beginning of the defense organization and enlargements of the army, the farm losses jumped to an average of 1,875,000 during the three years 1941-43. In 1944, this loss dropped to 676,000 and in 1945 it dropped still further, leaving a net increase of 800,000. The year 1945 was the first since 1933 in which farm population showed a net gain. Of the national increase in total population, the farms furnished about 380,000 per year while the former was increasing at the rate of about 1,000,000 persons per year. The other increase came from the excess of city births over deaths and from immigration.

There was also a growing seasonal change in farm population as people moved to farms in the spring and returned to the cities in the fall. This change during 1945 and 1946 was estimated to be about 800,000 persons. The total number on farms was about the same from July to October. The number of males on Jan. 1, 1946 was 13,-080,000 and females 12,750,000. The number of males over 14 years of age was significant as indicating the labour supply. In 1946 these numbered 9,080,000 compared with 11,449,000 in April 1940, before the army draft and the requirements for war industries had much effect. A year earlier the total was only 8,540,000, the low point in farm manpower. Those remaining on farms were of a higher average age because younger men had been taken for the military forces. The loss of 2,400,000 men 14 years and over from 1940 to 1946 was very significant to the farm manpower change. The fact that U.S. agricultural production increased so greatly during the war at the same time that manpower was declining,

Four-H boy and girl harvesting corn during the agricultural labour shortage of 1943 in the United States

was due to the use of more machinery, longer hours by the men who worked, more work by women and children, and the employment of imported workers and prisoners of war.

In 1940 the urban population produced only 74% of the number of children required to maintain a stable population, while the farm population produced 44% more children than were required to maintain rural population. This farm surplus was not sufficient to keep up United States population. The war was expected to change this situation, however, as the general birth-rate was increasing.

What the situation would be in another generation, if immigration was restricted and the farm population became stabilized at a fixed level with no surplus to keep up urban population, was a question yet to be answered. Forecasts indicated that, in accordance with existing trends, United States population would become stabilized about 1950 at about 150,000,000 persons, of whom 20,000,000 would be engaged in agriculture. Some rural sociologists expected the decline in farm population to become stabilized or even to increase following the food crisis of World War II. If the plans to promote better nutrition throughout the world through such agencies as the Food and Agriculture organization succeeded, there would be a larger number of people needed to produce the world's food. Previous surpluses had been largely excessive stocks in particular countries at the same time that more food was needed elsewhere.

The decline in persons engaged in agriculture had been world-wide, however, along with the growth of industrialization. Some of these changes were of timely significance in view of the new emphasis being put on food production to meet all needs. In Great Britain, one of the first countries to be highly industrialized, the population gainfully employed in agriculture declined from 13% in 1881 to 9% in 1900 and to 6% in 1931. In Germany the decline came later, from 42% rural workers in 1882 to 26% in 1939. France changed less, from 44% in 1896 to 35% in 1931; Canada from 48% rural in 1891 to 31% in 1931. Estimates for the less industrialized countries of large population included the following: Soviet Union, 85% agricultural; China 80–85%; India 67%; Spain 57%;

Italy 48%; Japan 49%; Brazil 66%, and most of the Balkan countries 75–85% agricultural. The proper balance between industry and agriculture was beginning to be a problem commanding the attention of the world's economic organizations. The growing organizations of rural people raised the question at several international meetings in 1945 and 1946. Plans were made in London in May 1946 to develop a world-wide agricultural producers' association or union to include the peoples on the land in all nations. The total number of these was estimated between 1,000,000,000 and 1,250,000,000,000, or more than half of the world's population.

Labour and Wages.—The labour supply on United States farms declined with the total number of persons on farms from 1937 to 1946. The average of total family and hired workers in 1935–39 was 10,920,000, of which 8,353,000 were family workers and 2,567,000 hired. By 1941 the total had declined to 10,361,000 and by 1945 to 9,844,000. In 1945, with the return of men from the military forces, the numbers increased about 100,000 and by June 1946 the total was about 4% more than a year earlier. The variation was more with hired labour, the number of which got as low as 1,320,000 in early 1946. About 1,000,000 returned veterans were at work on farms in June 1946. Fewer foreign nationals were at work, and no prisoners of war were employed on farms after July 1, 1946.

With the government's appeal for greater production in 1941 the call for more labour arose at once. The call for help by war industries began to be noticeable in 1940, and by Jan. 1942 estimates indicated that more than 2,800,000 had changed to nonfarm jobs and 283,000 had joined the military forces. A year later, in Jan. 1943, the losses to agriculture were estimated at 3,498,000 to nonfarm jobs and 1,012,000 to the armed forces. The change was less rapid through 1943, and in Jan. 1944 the total loss to the farm labour supply was put at 5,127,000. Included in these totals were many formerly unemployed or not ordinarily counted as farm labour; many were women, and the absence of many was offset by children who began to do full-time farm work. The transfer out of agriculture of full-time adult workers with useful farm experience was probably about 2,000,000, since the total reported as employed on farms in 1945 averaged 9,844,000 compared with 10,585,000 in 1940.

Military deferments were granted to farm workers in 1942; and by July 1943, 1,449,000 farm workers in the 18-37 age group were placed in deferred classes. This stimulated a small shift back to the farms of workers who had left for city employment. The War Manpower commission encouraged men with farm experience to return to the farm, and also issued regulations to restrict the movement of farm workers to nonfarm jobs. The secretary of agriculture was allotted funds to move agricultural workers to points of critical need, and considerable numbers of men were so allocated. In 1943 the Agricultural Extension service assumed leadership in mobilizing all labour resources in rural areas. In April 1943 the sum of \$26,100,-000 was appropriated for the War Food administration to assist farmers to meet their labour needs. A United States Crop corps was organized, and the Woman's Land army and Victory Farm volunteers were started to recruit women, boys, girls and men not fully employed at nonfarm work. Training camps were established to instruct these recruits in farm work. There was a total of several million workers in these classes. Other sources of farm labour were Japanese internees, conscientious objectors and soldiers on leave. Most of the foreign labour brought in was Mexican and Jamaican or Bahamian, about 178,000 in all, and 70,000 prisoners of war.

A problem in 1945 was the low wage level of farm labour compared with what the war workers had been getting. Few were willing to return to the farms at the lower wages. War veterans who were receiving \$20.00 per week in uniemployment insurance payments would not take farm jobs at a lower wage. Houses were an inducement to married men, but these were scarce. Even when higher wages were offered, many servicemen preferred to continue looking for better nonfarm jobs. The number of hired workers as a whole was about 7% larger on July 1, 1946 than a year earlier.

A scarcity of workers was still in evidence in some areas in the harvest season of 1946, although wages were higher.

Farm wages as a whole declined from 1937 to 1939 and then advanced to more than double the average of 1935–39. Hired men averaged \$28 per month without board and \$36.32 with board in 1937, compared with \$92 without board and \$106 with board in July 1946. The upward trend was faster than the rise in farm prices, which advanced to 218% of the 1910–14 base of 100 by July 1946, while wages had advanced 390%. Farm wages were stimulated more by the rise in city wages than by the advance in farm prices. The rapid advance in farm wages began in 1940 as the demand for workers in war industries started.

The area of highest wages was the Pacific coast states, where the index rose to 426% compared with an average of the other regions of only 335%. The smallest increases were in the east south central states, where it was only 290%.

Authority to stabilize wages of agricultural workers,

Unpredictable horn of plenty upset the best-laid plans of 1938 crop control, according to Sykes, who entitled his cartoon in The Philadephia Evening Public Ledger, "Overwhelmed"

given to the department of agriculture in 1942, applied to those earning less than \$2,400 per year. Only a few orders were issued establishing ceilings for farm workers, mostly for California processed crop workers. An order was issued by the Director of Economic Stabilization providing that no employer could decrease wages below the rate paid between Jan. and Sept. 1942 without the approval of the War Food administration. The general level of farm wages was considered substandard. Efforts to organize farm labour appeared before World War II but were strongly opposed by general farmers' organizations and made no substantial progress except in connection with highly specialized operations such as fruit picking, packing, etc. The fact that more than half the total U.S. agricultural production for sale was produced by 10% of the farms indicated that commercial farming was rapidly concentrating into larger units, and that hired labour might become subject to organization. The fact that the typical U.S. farm was a family enterprise was still the stabilizing factor.

While wages varied with the skill of the worker, the promotion of fixed union-hour rates would be difficult to establish. Gross production per farm worker in the United States was 14% greater in 1939 than in 1919, and by 1944 production was 26% greater than in 1939 because production increased 18% and farm employment decreased 6%. The greatest advance was made in the central states, where the introduction of new machines had been greatest. The gain was least in the middle Atlantic and east central states.

The paradox of the war period was the fact that fewer farm workers did a bigger job of production, although several million of the most able-bodied and skilled men left the farms to join the military forces or to work in war industries. Their places were taken by less skilled men or women, children or older men who had practically retired but returned to duty in the war emergency. The average quality of the labour declined about 5%.

Tenancy.—A problem of national concern was acted upon in 1937 when the Bankhead-Jones Tenant act was passed by congress to help landless farmers buy farms. This act authorized loans to farm tenants to purchase farms and repay in 40 years at 3% interest. The farms were to be under the secretary of agriculture for the first five years after purchase, and he might supervise the farmer's operations until the loan was paid in full. In 1930, about 42% of farms were being operated by tenants. By 1940 the number of tenants had decreased slightly to 39% of the total number of farms. In the first year 1937-38, about \$10,000,000 was loaned to 1,840 men to buy farms that cost an average of about \$5,000. By 1940 about 13,250 tarmers had been helped to ownership. As the defense industries attracted labour from the farms the number of tenants decreased. By 1945, nearly 38,000 tenants and share croppers had been helped to buy farms. While this number was not a great part of the 2,500,000 tenants in the whole country, it represented a check on a bad trend. The success of the greater part of these new farm owners was shown by the fact that in 1945 some 66% of the borrowers were ahead of schedule with their payments. Half of the \$50,000,000 made available for farm purchase loans in 1946 was earmarked for World War II veterans. Because of the rise in farm land prices, greater care was exercised in aiding buyers. The average cost of the farms bought in 1945 was \$5,942 compared with \$5,994 in 1944 and \$5,721 for the period 1938-43. Only \$11,699,000 of

the \$15,000,000 available in 1945 was used because good farms could not be found at prices considered satisfactory. The experience of eight years showed that an efficient family-farm could produce a gross income of \$1,500. Loans were also made to farmers to enlarge their farms. With the increasing size of farms, the opportunity for young farmers to get a start was becoming more difficult unless they worked for the large farms for hire. A new class of skilled farm mechanical workers was appearing. These men lived in towns and villages and drove to their jobs in the country. Their organization into unions was foreseen and was attempted in some cases. In areas of highly specialized agriculture this new development was particularly significant.

Farm Security.—The Farm Security administration was created in 1935 and got into full operation in 1937. Created to help low-income farmers, it started as a subsistence program when thousands were without adequate income and evolved into a rehabilitation program that became less urgent when the war began and farm prices rose. About 1,000,000 farm families which were on relief in 1933 were not much better off in 1935. Loans were made to put these people into a position to recover normal incomes. During 1939, about \$20,000,000 was spent as direct assistance to destitute farmers from the drought states and other areas of crop failures. Rehabilitation loans were made to families to buy work stock, meat animals and other essentials to improve their production for living. In 1938, some 232,947 families each added \$269 to their net worth. Thousands were helped to obtain leases at longer terms on the farms they operated. In 1938, more than 18,000 advanced from the status of share cropper to

The homestead project was started in the interior department and later transferred to the Farm Security administration. These projects numbered 175 in 1939 in housing and farming, with a total value of more than \$100,000,000. About 14,000 families were provided with farms and homesteads, and camps for migrants provided for 6,500 other families. This was not a strictly agricultural project but involved considerable relief for suburban families and labourers in the vicinity of industrial centres. The Subsistence Homesteads projects numbered 42 in 14 states for 2,308 families. By 1941 there were 151 homestead developments. Considerable public criticism arose as to the value of these projects. In 1941 the Farm Security administration began to sell them to private associations. By 1942 these projects were being liquidated rapidly, and the nonfarm projects were transferred to the Federal Public Housing authority. There were 142 farm projects with 9,218 units which were about half sold by July 1943. The care of migrant workers came to large proportions. Shelter for 15,000 families in 14 states was built in 1941. A program to improve the medical care of farm families was developed that aided over 100,000 farm families in 35 states. The system provided for health funds and made charges in relation to the size and income of the families. The whole plan, approved by the state and county medical societies, was chiefly available to FSA

Mechanization.—The use of the gasoline tractor on U.S. farms began about 1910 and after 1919 increased steadily in numbers, at about the same rate until 1946. In 1937 there were 1,230,000 tractors on the 6,300,000 farms, about half of which were suited to tractor use until new types of other machines to use with tractors were produced. By 1945 the number had increased to about 2,100,000 tractors. During the war years 1942–45, about 400,000 were sold to

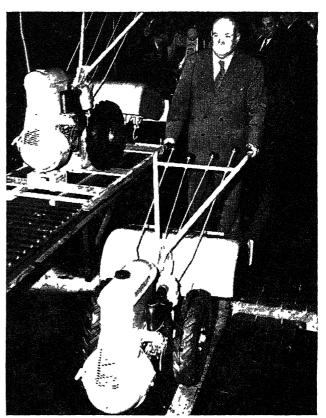

farmers although the shortage of farm machinery was acute. Farm trucks and automobiles increased less rapidly. The number of trucks was reported as 990,000 in 1937 and 1,080,000 in 1945. Automobiles increased from 3,962,000 in 1937 to 4,100,000 in 1945. Farmers could not buy trucks or automobiles except as rationed during the war years, but tractors were regarded as more essential to farm production.

The mechanization movement was greatly accelerated during the latter half of the decade by the shortage of labour. The demand for machines exceeded the supply at all times and led to farm machinery rationing in the fall of 1942 which continued until Nov. 1944. Not only tractors but new type machines operated by the tractors or under their own motors increased rapidly in use. Corn pickers were produced to the extent of about 14,000 per year from 1937 to 1943, but in 1944 25,300 were built. Combine harvester-threshers adapted to complete harvesting of small grains in the field, averaged about 45,000 machines per year from 1937 on. Pick-up hay balers were introduced in 1941; more than 12,000 were sold in 1944. Milking machines were in great demand, 21,500 being made in 1937 and 251,000 in 1944. This machine promised to be in almost universal use in larger commercial dairy farms within a few years. Other machines which increased rapidly in popularity during the decade were tractor cultivators, power sprayers and grinders, peanut pickers and field cultivators.

The newer machines were beginning to out-mode others; the corn-binder, for example, was giving way to the corn picker-shredder. Grain threshers were being replaced by combine-harvesters, etc. Early tractor machinery was mostly for plowing, disking and cultivation of crops. The later increase was in new harvesting machinery, with greater effect in labour-saving than the former. The tractor first operated to eliminate the horse and mule. After 1918, when horse and mule numbers were at 26,700,000, the decline was constant, to only 12,105,000 head on farms on Jan. 1, 1946. The newer types of machines were designed to save man-labour and were rapidly reducing the number of men required to handle a unit of land. It was estimated that about 50% of U.S. small grains were now harvested by combines, and 25.000,000 ac. of corn was harvested in 1944 with corn pickers.

The war production program for farm machinery greatly restricted manufacture to 83% of 1940 output in 1942. In 1943, a further drastic reduction to 23% of 1940 production stirred vigorous protests from farmers, and the quota was raised to 31%. Prices of used farm machinery rose as new machines became scarce, and the OPA in 1943 established price ceilings for five types of machines, whether sold by dealers or farmers. These were combines, corn pickers, corn binders, motor-hay balers and tractors.

Protests arose from the fact that large amounts of farm machinery were being exported. In 1946, a leading tractor manufacturer protested against the shipment of an order of 14.500 tractors by U.N.R.R.A. to southeastern European countries on the grounds that these countries had few machines to use with tractors, poor servicing facilities and practically no provision for the instruction of farmers in the use of tractors. The Civilian Production administration refused to change its plans and stated that it was trying to strike a balance between domestic and foreign demand. American farmers were said to be holding orders for 250,000 new tractors. The use of rubber tires on tractors presented another problem which was serious until the output of synthetic rubber was increased in 1944.

First rototiller off the assembly line at Willow Run, Mich., being inspected by J. W. Frazer. The new self-powered machine was designed for farms of small and medium acreage and put in production on March 26, 1946

The increasing use of farm machines affected the total farm output indirectly by reducing the labour and land needed to support horses and mules for farm power. This gain was estimated at 7% in 1944 over the prewar 1935-30 average. As machines were purchased and the number of horses declined, the crop area formerly devoted to growing horse-feed was used to produce crops or livestock products for sale. This was a national gain in agricultural output but not always a gain to the farmer, who had to buy gasoline, oil and services for his tractors. It was estimated that about 5,000,000 ac. were released from the production of horse and mule feed during the period 1942-44 inclusive. The replacements needed to maintain the tractor numbers on farms was estimated to be about 200,000 per year in 1944, and for a few years after World War II even a larger number would be required because of the lack of replacements during the war. New types of machines were making older types obsolete and were thus stimulating further replacements. The cotton picker was becoming more successful by 1946 and appeared to be on the threshold of mass production. Other new devices such as beet-toppers, flame-throwing weeders. etc., would reduce the demand for hand-labour and favour cheaper production.

Fertilizers.—The production and use of commercial fertilizers expanded about 50% during the decade 1937–46. An average of about 7,300,000 tons was used in the period 1935–39, after which period the output increased steadily to 12,055,000 tons in 1944, and 13,202,000 tons in 1945. Estimated in terms of active elements for plant growth rather than in total weight of the commercial mixtures, the consumption in 1944 was 1.8% of the prewar amount. The trend was toward mixtures of higher plant-food

analysis; hence the amounts used might not fully represent the increase in plant-food applied to the crops. Fertilizer manufacture was maintained during the decade much better than in World War I because of the existence of other domestic sources of raw materials. The AAA promoted the use of fertilizers both in prewar and wartime periods.

Nearly half the total consumption of commercial fertilizers in 1937 was in the south Atlantic states, with North Carolina far ahead of any other state. The south central states came second, with Alabama leading. The cotton belt used about half of the total output. The north central states in the corn belt had not yet begun to use commercial fertilizers except those states on the eastern border-Ohio, Indiana and Michigan, although soil experts had been advising the use of applied fertilizers to establish grasses and clovers. The north central states led in the use of lime, however, consuming in 1944 about 14,000,ooo of the United States output of 23,800,000 tons. The one state of Illinois used nearly 4,000,000 tons of lime fertilizers. Total United States use of liming materials increased from 7,199,000 tons in 1937 to 23,828,000 tons in 1944.

The world's fertilizer production was seriously upset by World War II. European countries, normally large users, were in most cases cut off from their sources of supply, and crop yields declined. One of the first relief efforts was to restore fertilizer shipments in Europe. Despite large supplies of potash in Germany and phosphates in North Africa, nitrogen from synthetic plants was short because of the destruction of most of these plants.

Crop Insurance.—This type of insurance was first made available to farmers on the 1939 wheat crop and the 1942 cotton crop. Crops had been insured against such weather damage as hail in previous years, but no system of insuring against loss of yield had been tried on a large scale. This idea had long been discussed as a possible means of removing some of the risks of farming and assuring a more stable return. Private insurance companies had made some experiments without widespread success. It appeared to be a service that should be a function of the federal government so as to spread the risk widely over the country and thus lower the premium rates to reasonable limits. The Federal Crop Insurance corporation began as an agency of the United States department of agriculture, assisted by other agencies in its early trial work and employing practical farmers to assist in local administration.

In 1943, congress provided no funds except for the liquidation of contracts outstanding. The reasons given for the discontinuance of the insurance by congress were that the majority of farmers had not accepted the plan in the counties covered, and that losses exceeded premiums on wheat by 50% and on cotton by 66%. This loss was due to covering some counties that had exceptionally poor crops, and to the lack of data on which to base reasonable premiums. Experts stated that 10 to 25 years' experience would be needed to determine the lowest safe rate of premiums. This lack of action by congress aroused such widespread protest among farmers that in Dec. 1944 the Federal Crop Insurance act was amended to restore the program of experimentation and insurance. Insurance was not available on the 1944 wheat or cotton crops, nor on the winter wheat crop of 1945. The new law extended the coverage to flax and authorized trial insurance in 1945 to corn and tobacco in a limited number of counties. It also provided that each year thereafter trials could be started on not more than three other crops each year. These trials were limited to 3 years in 20 counties to gain experience. The insurance was against losses due to unavoidable causes. On wheat, cotton and flax the insurance was against loss of yield at either 75% or 50% of the long-time average yield of the farm. The premium and indemnity were determined in units of the crop such as bushels of wheat or pounds of cotton, and payments by farmers were usually made in cash. On the trial crops two plans were offered. One was against loss of the farmer's investment, with 75% coverage. The second plan was for loss of 50% of yield as in the case of wheat, cotton and flax. In the case of tobacco, growers were also insured against loss of quality as well as yield.

Premium rates were generally made uniform for all farms in a county. The cost of administration was paid by the federal government. Provision was also made whereby the amount of insurance increased with the progress of the crop. If the crop was destroyed early in the season, the protection was only about one-half of what it was at the time of harvest. Excessive losses on abandoned acreages were thereby avoided. One-sixth of the nation's wheat acreage had sometimes been abandoned, although the acreage often had been planted later to other crops. The principal problems were to secure larger participation by farmers, to spread the risk over several years, and to determine what the average risk was for each region and crop.

The extent of the use of crop insurance was shown by the records of acreage covered and production insured. In 1939, wheat insurance began on 7,010,000 ac. operated by 165,775 farmers with a maximum production of 60,-826,000 bu. The cost in premiums was 6,670,000 bu. The insured units increased to 400,043 in 1942, covering production of 88,063,000 bu. The crop of 1944 was omitted, and the coverage of 1945 dropped to 25,653 farms on spring wheat only. The cotton program began with 169,-072 units in 1942, covering 407,612,000 lb. of cotton. The amount covered was slightly less in 1943 and in 1944 was omitted. In 1945, cotton insurance was resumed on 113,760 units covering 280,531,000 lb. Flax coverage in 1945 was on 40,419 units and 3,738,000 bu. of flaxseed. On corn the 1945 season covered more than 12,000 farms in 15 trial counties. Tobacco trials covered about 12,500 farms in 13 counties. Early reports indicated that about 500,000 farms would be covered by crop insurance in 1946. All participation was voluntary, but insurance was not provided in a county unless at least 50 farms or one-third of the farms growing the crop to be insured agreed to participate. Areas of excessive risk might be refused pro-

Agricultural Co-operation.-The progress of the cooperative movement among United States farmers was steady and continuous through the decade 1937-46. The number of organizations declined slightly, but the real measure of the movement was the number of members and volume of business. The total membership of marketing and purchasing associations was estimated at 3,200,000 in 1939 and 4,390,000 in 1944. The growth was most rapid among purchasing associations, which included more than a third of the total in 1944. The volume of business was estimated at \$2,087,000,000 in 1939 and \$5,160,000,000 in 1944. Of this total the larger part, \$4,430,000,000, was done by marketing associations. The dairy co-operatives led in both number of members and volume of business. The livestock associations came second in membership, but the volume of their business was less than that of the grain associations. The dairy and grain co-operatives accounted for over half of the total business, and also numbered about half the associations in the country.

Aside from the marketing and purchasing associations mentioned, several other types had become important. Farmers' mutual insurance companies -numbering more than 1,900 had about 3,000,000 members. These companies had nearly \$13,000,000,000 insurance in force in 1942 with reserves of over \$55,000,000. More than 800 rural electric power co-operatives had been organized in the decade, with about 1,500,000 members. Mutual irrigation associations with 175,000 members and 2,000 farmers' co-operative telephone companies with 500,000 members were some of the more important groups. There were also several thousand other types of small co-operative associations serving farmers.

Agricultural co-operation appeared to have become stabilized after 1930 as a form of service well suited to farmers' needs. After the booms in co-operation of the 1880s and 1930s the excessive claims for co-operation subsided. Federal and state legislation encouraged and regulated co-operation among farmers so that there was no struggle during the decade 1937-46 comparable to that in the 1920s for protective legislation. The only late development was the organized effort on the part of some new organizations to secure the revision of the tax laws as applied to co-operative associations. These attacks were based upon the charge that co-operatives had an unfair advantage over private enterprise since their patronage refunds were not taxed as were profits from corporations. The true co-operative was not operated to make profits but merely operated a service which was charged to the member at cost. Profits were not made as from an investment in a corporation. The trend during the decade was toward the consolidation of local associations into statewide, regional and national organizations for more efficient management. The activities of some co-operatives broadened into the ownership of factories to make supplies, mix feeds and fertilizers, etc., as services to their members. These activities also were not operated for profit but entirely as a service to the members. Some co-operatives entered the oil distributing field, as this item had become important to farmers with the increased use of motor-driven machinery. These new activities stirred up some criticism from privately-owned industries. The idea that co-operative organization could assure farmers higher prices through control of large proportions of certain crops had generally been abandoned as a fallacy.

Co-operatives assisted the government effectively during the war period in programs on marketing, storage, etc. These organizations had become a national factor in developing policies for agriculture through their national council, one of the large organized groups of farmers. The financial servicing of co-operatives was placed under the Farm Credit administration, which also controlled the banks for co-operatives. This system included the Central bank and 12 district banks. Loans by these banks to cooperatives were \$97,585,000 in 1937 and increased steadily to \$398,581,000 in 1943, when the volume of farm products was high. The co-operative research and service division of the Farm Credit administration provided a clearing house of technical and administrative service for all cooperatives. An example of such work on wartime problems was that of training sheepmen to prepare sheep pelts to make warm suits for the air forces. As a result of this campaign, some 2,000,000 more pelts than normal were secured. Many studies in co-operative plants resulted in the introduction of new methods that aided in the war effort.

Research and Education.-The state and federal agricultural experiment stations, agricultural colleges and extension services became important agencies during World War II to organize and assist the food production campaign. Using the experience gained in World War I, they had the results of a quarter-century of research to guide the new programs. During these years, tens of thousands of tests and trials had been made. The agricultural colleges had turned out trained graduates, and the extension service had contacted, through its county agents, almost every working farmer in the nation. No nation had ever been so completely organized and trained. Large appropriations for research and education by both federal and state governments had expanded these activities steadily. One such act of congress passed in 1945 provided \$12,500,000 more federal funds to be matched by state funds on the three following years and to be expended almost entirely in counties. The extension service organized more than 1,700,000 teen-age boys and girls for light farm work through the 4-H Clubs.

Foreign Trade.—The foreign markets for United States agricultural products seemed to be disappearing at the beginning of the decade 1937-46. This was due to the growing self-sufficiency policy in Europe, the competition of other exporting countries with lower prices, and the decline in the volume of United States agricultural production from 1931 to 1937. In food products alone, imports exceeded exports from 1923 to 1940, when the net imports amounted to 3% of domestic production. The United States government in 1937 was using the agricultural adjustment program to bring certain crops into line with needs and was also promoting Reciprocal Trade agreements, authorized in 1934, to increase trade by reducing tariffs. Up to the outbreak of World War II, these agreements were negotiated with 20 countries which in the past had provided outlets for about 60% of U.S. agricultural exports. With the outbreak of the war and the beginning of lend-lease operations, other trade controls were obscured, and the operations of international agencies of the United Nations, such as the Combined Food board, dominated. International co-operation began to take form in the making of agreements on specific products. A new wheat agreement was worked out in 1941 and 1942 between Great Britain, the principal importing country, and the leading exporting countries-Canada, Australia, Argentina and the United States. This was revised again in 1946 with 13 nations participating. Preliminary discussions were held on cotton, but no agreement had been made by the end of 1946.

Special agreements on sugar, coffee, cocoa, rubber, etc., were a part of the Allies' war planning and were to extend for the duration of the war emergency.

The volume of agricultural exports had reached a peak of nearly \$4,000,000,000 in 1919 and then declined almost continuously to only \$682,000,000 in 1938. This was 23.7% of total U.S. exports. During the same period, agricultural imports declined from a high of \$3,409,000,000 in 1919 to a low of \$613,000,000 in 1932 and then recovered to \$1,155,000,000 in 1937, which was about the average for the following five years. This was about 25% of total imports. It is important to note that almost exactly half of these agricultural imports were of products also produced in the United States while the other half was of products not produced domestically. The latter included rubber, coffee, cocoa, silk, wool, bananas, tea and spices.

With the beginning of lend-lease in 1941, commercial

exports declined still further until 1945. The volume of lend-lease exports rose to over \$1,000,000,000 in 1942; \$1,800,000,000 in 1943; \$1,600,000,000 in 1944 and about the same in 1945.

Lend-Lease.—The share of agriculture in lend-lease (q.v.)was of more importance than the relative dollar value showed. The amount supplied by the U.S. may have made the difference between victory and a breakdown in Britain and shortened the war by supporting the U.S.S.R. While the total value of foodstuffs shipped amounted to \$5,370,-644,000 to the end of 1945, it made up 10% of the total of nearly \$50,000,000,000. The proportion of food to the total of lend-lease declined after the first year. The United States shipped 6% of its meat supply, chiefly pork, in 1942; 9.3% in 1943 and about 7% in 1944 and 1945. Of dairy products, cheese and dry skim milk were most important; 22.8% was shipped in 1942; 14% in 1943; 23.2% in 1944 and 10% in 1945. Eggs, fats and fish were next in volume. Of dried fruits, the part of U.S. supply shipped rose from 14% in 1942 to 25% in 1945. In 1944, the high year of shipments, 6% of the record supply was sent to U.S. Allies-about 3% to Britain and 2% to the soviet union. Offsetting these exports, considerable food supplies were received by U.S. military forces from Australia, New Zealand and India, amounting to about \$300,-000,000 in value. Of the total shipments, about 60% went to Britain; 29% to the soviet union; 7% to the North African and Middle East area; about 3% to China-India area and less than 1% to other countries.

Total agricultural lend-lease aid reported from March 11, 1941 to Dec. 31, 1945, including food and other products such as cotton, tobacco, seeds, etc., amounted to \$6,060,746,000. At the same time, the value of reverse lend-lease received amounted to about \$800,000,000. Agricultural products were included in other classes of goods such as clothing and military supplies, so that the net total of United States agricultural aid was not much less than 10% of the grand total of \$49,096,125,000 as reported. Some additional shipments to China in 1946 slightly increased this total. Final settlement of the many lend-lease operations were not completed by the end of 1946.

Food and Agriculture Organization.—The progress in the science of nutrition was moving rapidly forward when the decade 1937-46 began; it received a powerful stimulus from World War II. The close relationship of health, food and agriculture had been emphasized by the health conferences at the League of Nations and by the rapidly developing science of nutrition in Great Britain and the United States. When the world-wide food crisis developed in 1939, there were immediate suggestions that an international movement should be organized. As a result, the United States government called 44 of the United Nations to a conference at Hot Springs, Va., May 18-June 3, 1943, on the food problems of the world. Four general objectives were agreed upon: (1) to raise levels of nutrition and standard of living of all nations; (2) to improve the efficiency of agricultural production and distribution; (3) to bring about co-operation among nations to achieve these objects, and (4) to exchange all scientific, technical and other information on action taken and progress achieved. It was also agreed to establish a new permanent international organization to carry out these objectives. Grants of funds were made and an interim commission was set up in Washington, representing the 44 nations to prepare a plan and constitution for the new organization. This

Piles of wheat in the streets of a Texas town in 1944, awaiting storage. Growers were forced to stack the wheat temporarily in the streets because of shortages of manpower, storage space and transportation

commission drafted and proposed a constitution in Aug. 1944 which was circulated among the nations for ratification. At the first assembly of the organization in Quebec, Canada, Oct. 16–29, 1945, the constitution was signed by representatives of 46 nations subject to ratification by their governments. The soviet union was represented by delegates but did not sign the convention. By Oct. 1946, 54 countries had shown interest in F.A.O. and 47 had been officially admitted to membership.

An executive committee was chosen and Sir John Boyd Orr, eminent nutritionist and member of parliament from Aberdeen university, Scotland, was chosen to be the first director-general. The interim commission was terminated and its headquarters at Washington and most of its staff were taken over as the seat of the new organization until the permanent seat of the United Nations organizations should be decided. The program of work was outlined to include nutrition, problems and research, agricultural production and marketing, the collection of world-wide agricultural statistics, the supervision of the world agricultural census, the collection and exchange of technical information and the general advancement of food distribution throughout the world. Forestry and fisheries were included within the scope of the organization because of their close relation to agriculture.

The budget of F.A.O. was set at \$5,000,000, limited to \$2,500,000 for the first two years. Quotas of contributions were set in relation to the various nations' ability to pay. Of the initial budget, the United States' share was 25%, Britain 15% and other nations in smaller amounts. The F.A.O. began to work closely with the United Nations, the U.N.R.R.A. and the Combined Food board on food problems. A conference was held at Washington in April 1946 on urgent food problems which resulted in the

reorganization of the Combined Food board into the International Emergency Food council with more member nations and a broader scope of operations. This council took over the duties of the Combined Food board and other agencies.

Because the scope of the F.A.O. embraced the field of work of the International Institute of agriculture, which had been the leading international agency for agriculture since 1905, the United Nations agreed at the Quebec meeting that the work of the institute should be absorbed. Accordingly, the nations which were members of the institute met in a general assembly at the seat of the institute in Rome, Italy, July 8-9, 1946, and adopted a protocol dissolving the convention of 1905 under which the institute was operated. Arrangements were made to take over the extensive library and archives of the institute; to employ or pension its staff and officially to conclude its affairs. The buildings of the institute, which were the property of the Italian government, were offered to F.A.O. for future use for a branch office. By this action the international collaboration of the nations for agricultural advancement began a new era, inaugurated 40 years earlier upon the initiative of an American, David Lubin, and under the sponsorship of the King of Italy. The second conference of the F.A.O. was held at Copenhagen, Denmark, Sept. 2-10, 1946. The organization was developed further on plans laid down at Quebec in 1945. The principal proposal for action was a plan for a World Food board to work for the better distribution of foods to nations in greatest need, and to plan for the improvement of the diets of people in many countries. A commission was set up to work out and suggest details of operation. The matter was to be referred to the member governments for turther consideration.

World Agriculture

In its relations to U.S. agriculture, world agriculture entered a new era during the decade 1937-46.

Although the foreign trade of the United States had shrunk to a low level during the interim between World Wars I and II, the conviction that national self-sufficiency was a fallacy in modern times came to be more widely understood by U.S. people. The Atlantic Charter declarations and other United Nations pronouncements on the world-wide nature of the food and welfare problem stimulated widespread discussion and thinking. The worldwide military campaigns of U.S. forces promoted acquaintances with conditions in foreign lands, and the returning veterans scattered their observations widely. The phrase "America can feed the world" had real truth notwithstanding the exaggeration. The enormous amounts provided for the Allies was the amount needed to squeeze through the war and turn the tide. A review of the contribution of the several Allied countries supported this view.

During 1942-44, United States exports of foodstuffs increased 395% and amounted to 33% of all the exports of the ten leading surplus-producing countries. Canada was second with an increase of 189% in exports amounting to 16% of the total. All other countries contributing to the food supply, including Australia, New Zealand, Brazil, Uruguay, Chile, Egypt, India and Argentina, contributed less exports than in prewar years. All except Argentina contributed less than 10% of the total. Argentina was the world's leading exporter of foodstuffs before the war but did not increase her production and contributed only 17% to the export supply in 1942-44.

With the great contribution to the world's food supply, the product of a quick acceleration. it was not surprising

that agricultural leaders should voice alaim as to the prospect of surpluses in the postwar decade. The record of agricultural production throughout the world during the war therefore became a matter of intense interest. In 1937, world food production was increasing at about the same rate as population. This increase continued through the war period up to 1943, after which the great losses in Europe caused a reduction in the world total. The great efforts of Germany and Italy to increase food production were being vigorously pushed in 1937 and with good results when not handicapped by bad seasons. The reduction of imports led to the consumption of more of the home-grown product in these countries. In general, however, Europe was better prepared for the war so far as good production was concerned than at any time since World War I. The extent to which German economy was organized for self-sufficiency was not recognized by the Allies until the war was well under way.

North America was the area of great expansion. Canada had a bad year in 1937 but made a phenomenal recovery in 1938. The United States increase was steady and rapid. South America as a whole increased production with Brazil making the greatest gain. Food crops were substituted tor coffee. In western Europe and North Africa, production held its own; the cereal crops were expanded after 1939 because a larger part of these could be used as food. Meat and egg output declined as soon as the blockade checked the imports of feed stuffs. The years 1940 and 1941 were unfavourable, and livestock numbers declined. There was a decline in the middle east except in Palestine and Turkey. In Australia, New Zealand and South Africa, the outlet of food products was limited by the shortage of shipping. Later the shortage of manpower held expansion in check, and the drought which began in 1940 further retarded output. In Asia as a whole there was relatively little increase in food production during the decade 1937–46. While reliable statistics were scarce the best estimates indicated that population had increased faster than lood supply. Almost all available land was being used and there was little chance to increase production except through better yields from larger use of fertilizers, better seed and cultural methods.

Canada.—In agricultural production, Canada remained in the class of Australia and New Zealand—countries producing the largest surpluses over domestic needs. Canada therefore played a heavy role in the food battle of the decade by providing her mother country with a large volume of food and other farm products. By close co-operation with Britain and good planning, exports were more than doubled by 1943 and increased even more in 1945 and 1946. By 1944 Canadian food exports had increased almost 200% over prewar years and made up 16% of the world's total exports, second only to the United States in output.

Canadian wheat usually accounted for about two-thirds of the food production of the country. The fact that most of the crop continued to be grown in the western provinces, where the seasons are variable, accounted for the wide fluctuations in production. The crops of 1940 and 1942 were nearly 90% above prewar production, while those of 1941 and 1943 were about 20% below the normal. With wheat comprising 66.7% of total food production, dairy products were second, about 10%; meat animals 9%; vegetables 5.6%; fruits 1.3% and the rest poultry, eggs and sugar of small importance. The wartime changes were principally in livestock products. Pork production steadily

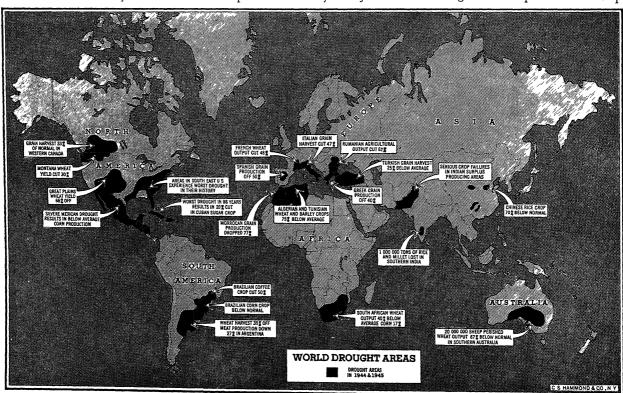

increased and had doubled by 1943. Cheese was increased a third and milk by one-fifth. Poultry and eggs were increased nearly 60%.

Mexico.-The agriculture of Mexico remained on a noncommercial scale during the decade, as most of the country's small farms were barely self-sufficient and produced no surplus for export. From the limited statistics available, corn provided over one-third of the total food supply, wheat 10% and beans and bananas each 5%. Livestock statistics were not available. Most of the poultry and dairy products were for local use, but large numbers of cattle were exported to the United States. While the country as a whole is usually very short of fats, large numbers of hogs are raised and killed for local consumption. During the decade 1937-46, Mexican farm production rose steadily; the increase was more rapid after 1940. In 1937, the banana crop for local consumption was only about half the average of 1935-39 because of a widespread outbreak of the leaf-spot disease. This loss was overcome slowly up to 1945. Corn, wheat, potatoes and beans increased from 1940 to 1946. The shortage of fats and oils led to an increase in oil crops, which became five times as large as in prewar years. Peanuts, sesame and cacao beans were greatly increased. Sugar production expanded over 50% and crops as a whole about 30%. Mexican fruits, vegetables and oils found their outlet to the United States since the shortage of shipping prevented shipping to distant markets. The special banana ships were taken for military uses, and transportation by rail, with limited refrigeration, resulted in large losses in transit. Shipments of fresh vegetables were also limited. Mexico increased the production of special fibre crops to quite an extent as an aid to the war effort. The Mexican cotton crop of about 500,000 bales was of the same quality as United States cotton and was sold largely by American firms.

Cuba.—About three-fourths of Cuba's exported products had been taken by the United States up to World

War II. Great Britain took 15% and the rest was mostly distributed among other West Indian islands. In 1937 and to the beginning of the war, Cuba was slowly increasing her output. Sugar remained by far the most important food product. Tropical fruits and early vegetables were increasing in importance in 1937 but dropped off sharply when German submarines appeared in the Caribbean area. Cuba imported all of its wheat and flour, 90% of its rice and most of the lard consumed. Because of the shipping shortage, Cuba became more closely linked to the United States during World War II. The strong demand for tobacco and its high price during the war brought added income to the island. The Cuban sugar crop averaged about 3,168,000 tons in 1935-39 and increased to a record crop of 4,741,000 tons in 1943, but the drought of 1945 cut production 20%. The country experienced great difficulties in 1945 as food supplies were short and shipping restricted. The Commodity Credit corporation purchased the four entire Cuban sugar crops during 1942-45, except for amounts needed for domestic consumption and some for other Caribbean Islands. This sugar was divided among the United States, Canada, Britain, the soviet union and other areas by the Combined Food board. The Defense Supplies corporation purchased the surplus of blackstrap molasses, mostly for alcohol making.

Caribbean Islands and Central America.—This region became the hunting ground for scarce tropical supplies like rubber, drugs, spices, etc., as soon as the war started. Before the beginning of the decade in 1937 the first steps toward the agricultural improvement of that area began with the extension of the good neighbour policy. The Pan American Union had attempted to promote agricultural co-operation between the hemisphere's countries with some success. An Inter-American Agricultural congress was a further step which developed into a broad program in 1943 and later. World War II advanced the movement and resulted in the creation of the Inter-American Institute of Agricultural Research at Turrialba, Costa Rica. By this joint effort the region was expected to develop

commercial crops that would increase trade and the income of the people on the land. Crops of sugar and tropical fruits were exchanged among the islands, and most of the surplus was shipped to the United States during the war years. The drought of 1945 severely reduced the production of all of the Caribbean Islands. In Central America the loss of the banana trade was the worst blow; recovery was beginning very slowly in 1946. Foodstuffs were imported in the period 1943-46 because of shortages resulting from the drought and the loss of exports with which to buy foods. This area had not attained a balanced selfsupporting agriculture except for the primitive rural natives. The exports of bananas, coffee and cacao were exchanged for wheat, fats and oils from near or distant countries. The city populations required more imported foods than the rural natives who were practically selfsupporting.

Argentina.-World War II brought about a change in the agriculture of Argentina. The wheat crop declined to almost a third below the prewar level, corn production was only two-thirds as great in 1946, and flaxseed gave way to sunflowers grown for oil. Following the end of hostilities the grain production was expected to recover. In the prewar period 1935-39, Argentina led the world as an agricultural exporting nation. This was due to its comparatively small population and large agricultural resources. The Allied blockade cut off trade with Europe except to Britain. The United States took wool, oils, cheese and casein; Britain took meat, and Brazil imported wheat. A surplus of grains accumulated when exports declined faster than acreage. Part of the surplus corn was burned as fuel for power heat when coal and oil could not be imported. The government supported grain prices and regulated the grain trade. Rice production increased until the country was nearly self-supporting in this cereal. The big demand for vegetable oil led to the expansion of sunflower growing until in 1944 it was almost 700% above the 1935-39 average. The oil-seeds crushing industry was expanded until the country had an export balance in vegetable oils by 1945. The country maintained its position as the world's leading producer and exporter of flax-

Animal production was maintained and expanded in some instances. Britain took large quantities of frozen boned pork as well as considerable beef. The United States bought canned meat for the military forces. Pork production increased nearly four times over the prewar period, thereby creating a market for part of the corn surplus. Beef and mutton production increased less. Cheese made the greatest gain, but all dairy products increased about 75%. In 1945, total Argentine food production was estimated at 96% of the 1935-39 period because of the drought that continued from 1944 through 1945. Pastures were damaged as well as crops, resulting in the liquidation of large numbers of hogs and some cattle. The new Argentine government made great efforts to increase foreign trade early in 1946. Decrees were issued governing the purchase and sale of oil-seeds and oils by the government, and prices were fixed for domestic and export sale. Grains, including rice, were under export permits. A bonus was offered for wheat early in 1946 which resulted in a large volume collecting in the hands of the government for export.

Brazil.—With the exception of wheat, Brazil had become practically self-supporting in food production. The large exports of coffee remained the bulk of export trade, and imports of agricultural products were small. The wheat came from near-by Argentina, although considerable wheat

flour was imported from the United States. In the prewar period, exports included a small amount of meat, sugar, fruits, rice, cocoa, cotton and cottonseed oil. Meat exports increased after 1939 to 1944, then declined during the drought. This drought was followed by floods in some areas in 1944 and 1945 and reduced both crop and livestock production. The Brazilian government fixed minimum prices for rice, beans, corn, peanuts, soybeans and sunflower seed. The citrus fruit industry suffered during the war because of the limited markets. Meat and sugar were rationed because of short supplies, although exports of sugar to the Allied countries amounted to about 50,000 tons annually. Total sugar production averaged over 1,350,000 tons during the war years compared with a prewar average of 1,155,000 tons in 1935-39. The area of grains and oil seeds was made possible by the reduction in cotton acreage. Cotton production had increased steadily to 2,075,000 bales in 1937 and continued close to that amount until 1945, when the crop dropped to 1,400,000

Coffee production in Brazil declined steadily after the beginning of the war. The average prewar crop, 1935–40, was about 23,000,000 bags; it dropped to 16,700,000 bags in 1941, 13,080,000 bags in 1944 and 9,500,000 bags in 1945. Exports declined to 7,280,000 bags in 1942, and then increased to 12,500,000 bags in 1945. The Brazilian government placed a tax on new plantings and an export tax to buy surplus coffee to be destroyed. From 1931 to 1943 the government bought part of each grower's crop for destruction and during this period more than 78,000,000 bags were destroyed. The possibilities for the expansion of coffee production were so large in Brazil that measures of control were expected to be continued unless the world's coffee market could be brought under an international commodity agreement.

Other South American Countries.—Uruguay produced a slightly larger total farm output during the latter half of the decade 1937–46, the increases being chiefly in sunflower seed and peanuts. Wheat production declined because of export restrictions, and there was only a slight increase in livestock, which suffered severely in the drought of 1945. The nation imported more than it exported.

Paraguay changed relatively little during the decade. The only export of importance was meat.

Chile's most notable change during the decade was an increase in rice production. By 1946, the output was nearly ten times the prewar average. This changed the country to the export basis, which amounted to more than 50,000 tons by 1945. Chile was self-supporting except for sugar and beef before the war. A surplus of exports in prewar years was changed to a surplus of imports during the war, although quantities of rice, beans, grains, lamb and mutton and fruits were exported. The sugar imports came largely from Peru and the live cattle from Argentina. The mineral output of the nation paid for the surplus food requirements.

Bolivia, not a self-supporting country in agricultural products, experienced difficulties at times during World War II in securing adequate imports. Agriculture suffered from the loss of its workers to the mines. In 1945, acute shortages of wheat, flour and meat developed from transportation difficulties. Wheat was shipped from the United States. Meat was brought to points of critical need by airplane. The crops of 1946 were expected to be short because of scarcity of farm labour.

Peru, like Paraguay, changed little during the decade.

An export surplus of sugar was produced in quantity slightly below the prewar amount. The country continued on the import basis and production, including that of cotton, did not increase because of labour shortage and scarcity of fertilizers.

Ecuador expanded her production of rice and cacao. As soon as shipping was available the output of bananas would be increased. The government aided the development of new rice and sugar lands through irrigation.

Colombia, a tropical country with a balanced production, continued to import and export little. Efforts to secure supplies of tropical products during the war led to some small increases in these exports.

Venezuela, another country with inadequate agricultural production, encouraged a very slow expansion of cultivated crops. The government attempted to expand corn production and increase the meat supply by limiting exports.

(J. C. Ms.)

Great Britain.-In 1931, Great Britain reverted from free trade to a protectionist policy, and by 1937 most of the important farm products were subject to one or other of the common methods of protecting agriculture; but at that time the international situation and the need to safeguard food supplies made necessary a new policy. Thus the Agriculture act of 1937 introduced a new principle of agricultural assistance in the form of the so-called "land fertility scheme," by which the state offered contributions to cover 50% of the cost of certain fertilizers and drainage operations (in 1939 this was supplemented by the offer of a cash bonus of £2 payable on every acre of old pasture or meadow land plowed up). The food (defense plans) department became a new branch of the board of trade. Finally, the ministry of agriculture and fisheries approached certain selected persons to constitute the countycommittees which were to function as the minister's agents in the event of war.

As a result of these developments farming in Great Britain in 1939 had "become in practically all its activities an assisted industry with controlled prices, no longer determined by the world market but sustained by contributions, direct or indirect, from the exchequer which in gross amounted to about one-fifth of the total value of the output from the land." (Sir Daniel Hall, Reconstruction and the Land.)

Nevertheless, certain important fundamental trends of development, dating back to the 1880s, continued. The dominant feature was the change-over from arable to grassland farming with the contemporaneous development of livestock husbandry. British agriculture was drifting away from the production of staple commodities such as wheat, second quality meats and butter and cheese-all commodities with world markets and world prices. By 1937-38, livestock and livestock products accounted for over 70% of the total value of the gross output of British agriculture. Moreover, dairy products accounted for 25.7% of the total farming output. The other major products in order of financial importance in 1937-38 were: horticultural crops (13.4%). pigs (10.3%), poultry and eggs (9.7%), sheep and wool (9.1%), cereals (6.3%) and potatoes (5.5%).

This preoccupation with the production of milk, poultry and eggs, and fruit and vegetables was made possible by two conditions: the first was the availability of ample imported supplies of the relatively low-priced human foods. Thus, in 1938 Great Britain consumed about £650,000,000 worth of food of which it produced only one-third. Milk

and potatoes were the only two important food products in which it was self-contained. In 1938, Britain was spending about £1,000,000 a day on imported human food, importing 76% of wheat and flour, 50% of meat, 72% of sugar, 91% of butter, 72% of cheese, 44% of eggs and 68% of raw fruit.

Secondly, the actual production of British farms was also dependent on the availability of cheap imported supplies of certain raw materials, especially animal feeding-stuffs and fertilizers. Roughly 25% of the feed consumed by farm animals and birds was imported at a cost of about £50,000,000 per annum, and before 1939 British farmers were spending some £8,000,000 a year on fertilizers of which roughly 36% had to be imported because there was no home alternative.

The magnitude of the task facing British agriculture at the outbreak of World War II was most effectively shown by a few simple comparisons with the position in Aug. 1914. First, there were 5,000,000 more people to feed, and the consumption of food had risen from 21,000,000 to 25,000,000 tons. Second, over 300,000 workers had left the farms. Third, nearly 3,000,000 ac. of land had been lost to agriculture and the arable area was down by nearly 2,500,000 ac. Fourth, there was a much greater livestock population—873,000 more cattle, 1,067,000 more sheep and 1,271,000 more pigs. Fifth, dependence on imports for both human food and livestock feed was in consequence greater than ever. But, sixth, the country had 3,000,000 tons less of merchant shipping to carry these imports.

The task of British agriculture in 1939, therefore, was to increase the domestic output of food and to save shipping space.

Wartime Organization of Agriculture.—At least four different ministries were concerned with the control of British agriculture from 1939 onwards-the ministries of food, supply, labour and national service, and agriculture and fisheries. The three former delegated most of their duties, if they concerned production, to the ministry of agriculture. The ministry of agriculture worked through the County War Agricultural Executive committees which were set up in every county throughout the country. The committees came into being immediately on the outbreak of war. The members were appointed by, and were directly responsible to, the ministry of agriculture. Each committee consisted of nine or ten members and was assisted by a paid executive officer (appointed by the minister) and a staff of technical assistants. The county committees worked through sub-committees and district committees. The subcommittees were functional; district committees were territorial, their members being local farmers appointed by the county committees and not by the minister, and they had no executive powers: they were in effect the last link between the minister and the farmer.

Contact between the county committees and the ministry of agriculture was maintained through the ministry's land commissioners. From 1940 onwards a small number of liaison officers, appointed personally by the minister, performed the important double function of interpreting policy to the county committees and reporting back to headquarters on reactions and developments in the counties.

The county committees were given very wide powers delegated to them by the minister of agriculture under defense regulations (in particular D.R. 62). In the exercise of these wide powers the C.W.A.E.C.'s activities could be divided into the following main categories:

First, the issue of directives to individual farmers to produce the annual requirements decided on by the ministry

of agriculture and the ministry of food. These targets were split up into county quotas and allocated between the district committees, thence to the individual farmer.

Second, the C.W.A.E.C.s were responsible for the granting of permits for the allocation of goods in short supply (a formidable task, since many important farming requisites were scarce, and needed careful allocation); for administering the scheme for the reservation or release of farm workers, and the registration and organization of machinery and threshing contractors.

Third, the committees rendered certain specific services. The more important were: the employment of a reserve pool of labour and machinery; the direct contracting for carrying out operations on farms where the farmers themselves were unable to carry out the directives; the reclamation of derelict land, the cultivation of common land and the running of farms where no suitable alternative tenants could be found; the execution of work and the supply of goods on credit under a goods and services scheme.

The committees were responsible, too, for farming efficiency in the counties, but the most important control function was concerned with the general oversight of farm management as such. Where inefficient farmers failed completely to respond to advice and encouragement they could be dispossessed, but only with the specific authority of the minister. The technical development sub-committees were specially entrusted with the administration of an educational and advisory scheme for farmers and laid the foundation of the national agricultural advisory service which came into being in Oct. 1946.

Finally, the C.W.A.E.C.s were also concerned with the administration and supervision of the many subsidy schemes, such as the grassland plowing grant; grants for liming, manuring, drainage and bracken eradication; acreage payments for wheat, rye and potatoes; grants for the installation of piped water supplies; subsidies for hill-sheep and hill-cattle; and schemes for the financial assistance of producers on "marginal land."

The Production Program and Its Achievement.—Effort was concentrated on the extension of the acreage under the plow. It was the accepted view that "one acre of average arable crops feeds far more human beings than one acre of average grassland, whilst one acre of average wheat saves at least as much shipping as seven acres of the best grass in England." A successful campaign was launched in Sept. 1939 for the plowing up of 2,000,000 ac. of grassland in England and Wales alone to be planted to crops for harvesting in 1940.

In the autumn of 1940, the minister of agriculture announced a more comprehensive program of agricultural development. Farmers were assured that they would have guaranteed markets and guaranteed prices for their produce for the duration of the war and for one year thereafter, but would be called upon to use their farmlands in the best interest of the nation. To make this program possible, a hurried farm survey was carried out in 1940, and in 1941 a new and comprehensive survey of every farm in the country was launched and the new "Domesday" records of the farms of the country became in due course the invaluable basis for the subsequent annual production plans in agriculture.

In these annual plans, the emphasis continued to be on increasing the arable acreage to the limit of the country's resources, and farmers were urged to plow up all available grassland. But an order of priority was now adopted for the products of agriculture. This was done in consultation with the ministry of food, and due regard was

given to the nutritional welfare of the nation, to the efficiency of production and to the shipping situation. The production of all the milk possible was placed as the first priority call on the farming industry; potatoes came second because of their productivity and general use; wheat was to be given first priority among the cereals, and sugar beet and certain vegetables were also ranked high in the scale of requirements. Farmers were also urged to grow as much cattle food as possible in order to make the attainment of the milk target possible from the resources of British farms. Finally, farmers were also urged to keep as many other livestock as was consistent with the above priorities, but beef-cattle and sheep were to come before pigs and poultry.

In translating the national policy to the individual farm plan, regard was given to the varying physical conditions of the farms concerned. But in general farmers were urged to grow the so-called "dual purpose" crops, suitable for both human and animal food. The extension of ley farming as-a means of guarding against the exhaustion of soil fertility was widely advocated and adopted, and from 1943 onwards greater attention was paid to the efficiency of livestock production and especially the management of dairy cows. A comprehensive survey of all dairy herds was carried out, and drastic measures were taken to cull uneconomic animals; every effort was made to raise the standard of the ordinary commercial herds to something more nearly approaching that of the best producers. From 1943 onwards, steps were also taken to prevent any further decrease in the numbers of pigs and poultry, and especially to preserve a nucleus of good breeding-stock for later development.

The year 1944 witnessed the peak of the wartime drive for increased products of priority foods from British farms. It was also the first year of the four years' plan for the industry announced by the minister in July 1943. The main features of this plan were (1) no further increase in the arable acreage to be attempted, (2) the plowing of old grassland and the reseeding of cropped fields to be continued in order to enlarge the supplies of animal fodder and (3) greater emphasis to be placed on the improvement of livestock and restocking of land for postwar development. The year 1945 heralded a very tentative return in the direction of peacetime levels, but international conditions in 1946 slowed down this return, and British agriculture continued to be dominated by a measure of planned control.

The material results of the wartime drive to increase the production of British agriculture are best shown by a few comparisons of the position in 1939 with that in 1944 when the drive was at its height. The more significant of these comparisons were as follows:

- (1) In spite of the reclamation of much waste land since 1939, the total area of crops and grass in the United Kingdom actually had fallen by 600,000 ac. This reflected losses of farm land to military and to other nonagricultural uses.
- (2) Nevertheless, on this decreased agricultural acreage the total tillage (i.e., crops and fallow) was increased by nearly 66%. In 1939, the area under crops accounted for only 28% of the total cultivated land (crops and grass), but by 1944 this proportion had increased to 47%. In addition, the acreage under "temporary" grass had been expanded, while "permanent" grass had been reduced from 59% to 38%. By 1944, nearly 6,000,000 additional acres had been plowed up and put under crops and nearly 750,000 ac. put under temporary grass.

(3) The following increases were achieved in the acreages planted to individual crops: wheat 82.9%; barley 95.5%; oats 51.8%; sugar beet 25.8%; vegetables 66.4%; potatoes 101.8%. In terms of food produced, the output of wheat, barley and potatoes was more than doubled, and there was an increase of one-third for sugar beet and vegetables.

(4) The acreage of fodder crops was increased by nearly 600,000 ac. or 40%. The bulk of the extra feed available went to maintain the production of milk and to offset the reduction in the import of animal feeding-stuffs which had dropped to only 156,800 short tons by 1943 as compared

with over 6,720,000 short tons in 1939.

There was also an outstanding expansion of flax production. The acreage grown for fibre in England and Wales in 1939 was trifling; in 1944 it had risen to 51,000 ac.; the acreage in Northern Ireland increased from 21,000 in 1939 to 125,000 in 1944.

(5) The cattle population was increased by nearly 700,000, which reflected the success of the effort to promote milk production, but there was a drastic reduction in other farm livestock. Thus by 1944 there were 6,300,000 fewer sheep, 2,500,000 fewer pigs and 19,200,000 fewer poultry.

(6) It was estimated that "the net output of human food from British agriculture had increased by at least 70% in terms both of calories and of protein. The outcome of this agricultural program, coupled with the control of food distribution was that, by 1943, it had become possible to maintain total food supplies at an adequate level while at the same time reducing imports of food by 50%, thus releasing an equivalent amount of shipping for other war purposes." (Statistics Relating to the War Effort of the United Kingdom, London, 1944.)

These achievements were accomplished in spite of the loss of about 100,000 regular male workers from the farms, which occurred notwithstanding certain measures taken to stem it. Thus calling-up arrangements for military service provided for the retention of all "key" farm-workers on the land. The most significant step affecting farm-workers since 1939 had been the progressive increases in their remuneration. Thus the average minimum rate of wages, which was about 34s. 9d. per week in Aug. 1939, was raised to 48s. in May 1940, to 60s. in Jan. 1942, to 65s. in Dec. 1943, to 70s. in March 1945 and to 80s. in July 1946.

The depletion of the agricultural labour force was partly made good by the recruitment of the women's land army, the enrolled strength of which was over 80,000 by the middle of 1944. In addition, farmers were assisted by schoolchildren and adult volunteers. In 1945 and 1946, they had to depend very much on prisoner-of-war labour. Finally, the execution of the task was made possible largely through the increase in mechanization and especially in the use of tractors. (From a figure of 50,000 tractors in 1939 there were 125,000 in use on British farms by 1943.)

Marketing and Price Policies.—On the outbreak of World War II the government, through the ministry of food, either purchased, or controlled the purchase of, most of the staple food products. Livestock, sugar beet and eggs were bought at fixed prices; other commodities were controlled either by price-fixing or by the licensing of traders.

It was the policy of the ministry of food to interfere as little as possible with the normal channels of selling farm products. The most drastic changes in marketing farm products affected livestock. The farmers sold their livestock to the ministry of food at designated centres licensed by the government, and at which the stock were graded.

Before 1939 there were 16,000 slaughterhouses in England and Wales alone, and the wholesaler purchased his supplies from any convenient market or farm. By 1944, only 750 slaughterhouses were operated by the ministry of food.

It was in the field of prices that the policy from 1939 onwards vitally affected the agricultural effort. This policy was designed to use the fixing of prices as a lever to direct production towards priority products such as milk, wheat, potatoes, and sugar beets. In some cases these prices were buttressed by payments of special subsidies over and above the fixed prices of the products, e.g., \pounds_3 an acre for wheat and \pounds_{10} an acre for potatoes. Thus the price policy was used as an instrument of social policy directing demand towards certain essential commodities.

In Dec. 1944 the government declared its intention to continue its wartime system of guaranteed prices and assured markets for farm products, and this policy was reaffirmed and developed in Nov. 1945. An important feature of the new policy was the establishment of a dual price system. There were "minimum prices" on the one hand, and the government ensured that the "actual prices" would not fall below the minimum levels. For the fixing of minimum prices a system of four-year overlapping periods with biennial reviews was adopted. Thus minimum prices were to be announced three to four years in advance for livestock and for livestock products, and 18 months before harvests for cereals, potatoes and sugar beets. The actual prices for all products coming under the plan were fixed in advance for 12 monthly periods after annual reviews to be held in February. Both minimum and actual prices were fixed with due regard to the need for the greatest possible efficiency and economy in methods of production. Account was also to be taken of any modifications in the character of the agricultural output which might be necessary to meet changing national requirements. Above all the attempt was made to reconcile a reasonable measure of price stability in the short run, with the need for price adjustments to keep production abreast of general economic conditions, an experiment calculated to eliminate the disconcerting fluctuations in farm prices within a given production period which, in the past, made farming a gamble and benefited neither producer nor consumer.

Union of South Africa.—Crop production was not on a high level at the beginning of the decade 1937-46. The droughts of 1940 and 1943 reduced crops below average, and the three short crops forced the country to adopt rationing in 1946 after most countries were recovering from the war. The demand for foodstuffs in South Africa during World War II was due to the need for provisioning of convoys en route around the Cape of Good Hope. A large number of prisoners of war were also sent to this area to be fed from local supplies. The major part of the farm output continued to be in crops for home consumption. Corn is the most important grain crop, of which a part is exported to neighbouring colonies, as it is the principal food of the natives. Fruit exports to Britain were restricted by the shortage of shipping, except for dried fruits, which expanded in output. Sugar production was expanded about 30% after 1940. Production of meat animals was increased as rapidly as the feed supply would permit. Imports from Argentina were contracted for in 1946 to make up the shortages. The government raised the price of wheat to encourage planting. Had the droughts not intervened, the southern part of the African continent would have been well provided and would have made a much larger contribution to the war effort.

Australia.—Self-sufficient with respect to almost all foods for a considerable period, Australia was also the world's second largest exporter of foodstuffs during the prewar period 1935-39, second only to Argentina. Crop production did not increase rapidly, but exports were maintained in spite of the droughts, and rationing was introduced in order to conserve supplies for war uses. Early in the war, shipping was so scarce that the long haul to Britain was difficult, but with the outbreak of war in the Pacific there was immediate demand for all farm products that Australia could produce. Considerable quantities were supplied to the United States forces under reverse lend-lease. Other supplies were needed by the Allies in the Asia theatre of war. The two-year drought in 1943-44 was a serious set-back, cutting production to two-thirds of normal. Because of the small population of Australia the draft of men for military forces and war industries brought on an acute farm labour shortage which made farm expansion difficult. Machinery was also scarce and fertilizers in short supply. The result was a smaller production of cane sugar. Fresh vegetable output was increased to meet the demands of troops. The demand for meats increased, and pork and mutton output expanded. By 1943 there were 35% more sheep and lambs than in the prewar period. Milk was used as fluid milk and cheese, and the manufacture of butter was severely restricted. The greatest gains in exports in 1945 were in beef, veal and pig meats, while mutton and lamb were about the same as in the prewar period. Butter exports dropped off, although cheese shipments increased. The rice area was increased and the product was mostly exported to Pacific areas cut off from their normal source of supply.

New Zealand.—Before World War II, New Zealand was one of the best fed nations, and in many ways among the most prosperous agriculturally. It was a dairy and livestock island that exported large quantities of meat and dairy products and imported wheat, fruits, sugar and minor necessities. Splendid pastures favoured the livestock industries. Since it was mostly a pastoral country, expansion was not easy to accomplish without plowing up grasslands. A large increase in vegetable production was stimulated by the United States Joint Purchasing board to fill the military requirements of that area. Production, consisting mostly of lamb, mutton and beef, increased

about 10% above prewar averages. The best year was 1941, after which there was a decline in 1942–43 followed by some recovery. Wheat acreage declined in 1945 and 1946 because of low prices and bad weather at seeding time. Rationing was maintained in order to assure adequate supplies for export. The total value of exports from New Zealand in 1935–39 was almost equal to that of Australia and amounted to about 9% of total food exports, about the same as Australia. This was accomplished by a farm population of about 164,000 in New Zealand, compared with about 574,000 in Australia. Considering their total populations, these two countries were the most important agricultural producers in the world.

Continental Europe.-At the beginning of the decade 1937-46, the agriculture of most countries on the European continent was in an improving situation. The efforts of Germany and Italy to put their food production in order after the low years following World War I had brought good results. The production of central European countries was up to a fairly high level, and every effort was being made by Germany in particular to become self-sufficient. The "Battle of Wheat" in Italy had increased cereal production, and the introduction of U.S. seed corn into the Po valley gave promise of further increases. All of the reclamation efforts had added to the food supplies, although little was available from the African colonies. Italy's war efforts in Ethiopia and Spain had been a drain on her resources and had retarded her development-a handicap which Germany did not experience. The Germans were utilizing all the scientific aid they could collect by sending missions into other countries, notably the United States. In 1928 an American Study commission had surveyed Germany at the request of the German republic to suggest what was needed to regain the losses of World War I and the four years of inflation that followed. The recommendations of this commission were utilized by the succeeding nazi government along with all other aid it could assemble to plan for the expansion of agriculture in 1932-37. The potato crop of 1937 was reported at 2,032,-000,000 bu. compared with 1,681,000,000 bu. average for 1930-35. Barley production was 167,000,000 bu. compared with 144,000,000 bu. average. Beet sugar production was up to 2,436,000 tons in 1937 compared with 1,837,000 average before that year. Other crops had been increased likewise. During the first four years of the war, 1939-43, the axis countries overran the richest lands of the soviet union and western Europe, and were in command of an immense food supply. The blockade by the Allies was less important than the blockade of Britain by axis submarines. The soviet union, which was about self-supporting at the outbreak of the war, lost its breadbasket with the German invasion and was in a serious situation. The soviet surplus was found to be much less than generally supposed and the loss of 40% of its best grain land deprived the soviet armies of sufficient supplies. The beginning of lend-lease shipments from the United States were directed to the armies and war workers.

The axis countries lost some of their imports of livestock feeds and reduced the numbers of animals accordingly, but on the whole the reduction was less than expected. Plans for rationing the civilian population according to age and type of work were planned before the war and favoured the armies and essential workers. By shifting consumption to those involved in the war and reducing the poorer and oppressed classes to mere subsistence, the food supply was made to meet all needs. The axis policy, to keep the

farmers on conquered land producing at normal levels, was followed in the Ukraine, the Balkan countries, Denmark, France and Norway. The Germans moved farmers and machinery into some areas to increase production. Elaborate plans for the consolidation of all European agriculture under German leadership had been carefully worked out before the invasion of Poland. Able-bodied men were taken from the farms, and most of the farm work was done by the old men, women and children. At one time it was estimated that 90% of the farm work of the soviet union was being done by these classes.

 Λ great shortage of food and other agricultural products developed in Europe after the intense bombing campaigns of 1944 by the Allies. The destruction of cities, railroads, storage centres, etc., destroyed the surplus stocks and prevented the gathering of crops from the farms. The city populations suffered while the farmers were relatively in about the same position as before the war. The farm labour, machinery, fertilizer and seed supplies were smaller, yet most rural people had better subsistence than those in the cities. U.N.R.R.A. and other relief activities were chiefly confined to the cities after the end of hostilities. The year 1944 was the lowest in food supplies, with 1945 and 1946 showing improvements. The soviet armies recovered the Ukraine by the middle of 1944 and began to restore production. About 65% of the crop area was planted in 1944. France showed an increase in 1944 and much more in 1945. In the Netherlands and Belgium the 1944 campaign retarded recovery and it was not until 1945 that any material improvement was recorded. Germany had a poor potato crop in 1944 and began to feel the pinch for lood. Most of the supplies of Italy were taken by the Germans, leaving Italy very short of supplies. Altogether Europe was estimated to have only 85% of its prewar supplies, mostly in the hands of producers; the cities were very short in reserves.

The year 1945 brought the farm production of Europe

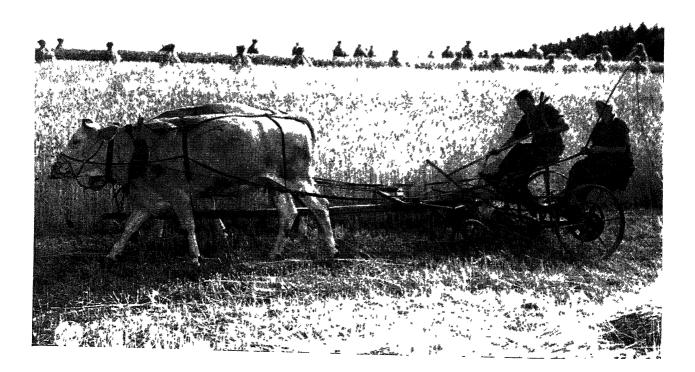

as a whole to the lowest state of the war, because bad weather and the final campaigns of the Allies followed a severe winter. The drought that swept all the Mediterranean basin reduced grain and pasture production. The Danube basin area was in a political turmoil which retarded all activities. Germany was breaking down, and the Low Countries were just beginning to recover. Broad estimates based on the scanty statistics available placed German agriculture at the low point of the century, perhaps 25% below prewar. Yields were down 20% to 25% and acreage 10% to 15%. Stocks were almost exhausted, and imports were wholly cut off. By the fall of 1945, planting in Europe began to recover and in the U.S., British and French occupation zones relief to farmers of seeds, machinery and fertilizers began to increase. The situation in the soviet zone was not fully reported but appeared to be improving. Livestock production was below prewar in all zones of Germany. Total agricultural production was estimated at about 25% below the prewar average. The 1946 mid-summer reports indicated that crops in 1946 would bring the level up to about 80% of prewar average.

Finland was about 20% short of being self-supporting in the prewar years. The Russian invasion of 1939 reduced the crop and livestock output sharply. Then the difficulties of getting imports increased and average consumption dropped about 25%. In 1944, when Finland gave 10% of her crop area to the soviet union while retaining her entire population, the situation was made much worse. The outlook in 1946 was for slow improvement until trade could be resumed that would assure imports.

Sweden was about 90% self-sufficient in 1937 even with sugar. As feed imports were cut off by the war, meat exports ceased. By careful rationing the food shortage of about 12% was controlled, and such products as milk, potatoes and vegetables remained unrationed.

Norway suffered greatly during the period of occupa-

German farmers reverted to primitive methods of agriculture after Germany's defeat, to compensate for lack of machinery and horses. Here a farmer and his wife are shown harvesting wheat with a pair of oxen near Honad, Germany

tion by the Germans. Only about 43% of its food had been produced within the country, supplemented by imports and fisheries. When the Germans limited the fishing and foreign trade became impossible, the shift was to a vegetable diet. Meat production stopped and only fish was eaten. Potato production took the place of grains. The recovery was proceeding slowly in 1945 and 1946 while fishing was being restored.

North Africa and Middle East.-North Africa exported considerable agricultural products up to 1942 and then with Allied invasion shifted to an importing region. The crops of 1942-45 were below average, and even good crops in 1946 were not expected to put the area on an export basis, since the population had increased from 16,000,000 in 1936 to more than 20,000,000 in 1945. The entire middle east had small surpluses after 1940 and was recovering slowly in 1945. Palestine, as usual, had to import heavily to support its rapidly growing population, which increased from 1,300,000 in 1935 to 1,800,000 in 1945, or $46\frac{67}{10}$ in 10 years. The usual exports of citrus fruits ceased during the war. The 1945 crop was estimated at 8,200,000 cases, of which 6,200,000 cases were available for export. The agricultural development of this country was at a standstill through 1946 because of the disturbed political situation. Until there was more irrigation the resources of the country would continue short of needs. Over the near east, Egypt, Turkey, Iran, Iraq, the agricultural situation was less disturbed than in Europe and was nearer to the prewar level in 1945 than elsewhere in the Mediterranean basin.

Soviet Union.—The agriculture of czarist Russia had produced a large volume of exports which gave the nation a leading place as an exporter of farm products. Following World War I and the subsequent revolution, the economy of the country was so disturbed that recovery was slow and the output of crops and livestock yielded little for export. By 1937 the production of livestock was still below the level of 1928 although the population of the country had increased about 10%. The country was about self-sufficient but on a low level of consumption. The German invasion of 1941 struck at the best agricultural region of the country, and about 40% of the best crop area became a battlefield. In 1941 and 1942 the soviet union lost control of its best wheat, sugar beet and oilseed areas. Much of the machinery introduced under the system of collective farms was located in these fertile areas, and much of it was lost. Reported losses included 137,000 tractors, 49,000 combines, about 2,000,000 plows and other small instruments. Great damage was done to seed and animal-breeding stations, sugar mills and transportation facilities. Livestock losses were heavy, although the soviets moved as many as they could to other areas. The manpower of the area was reduced by army drafts and the shifting of men into Germany as prisoner labourers.

The production of the area was maintained to some extent by the old men, women, children and town people. The Germans favoured the production of food crops and moved in tractors and other machinery to some areas. Yields declined and the soviet food supply could not be maintained in the uninvaded regions. Lend-lease shipments by the Allies, mostly by the United States, in fats and oils was equivalent to half of the 1938 production. Meats shipped were equal to one-fourth of soviet production; other foodstuffs not usually produced there were also received. These supplies went to the armies almost entirely, and the civilian population had a very small ration. Rationing was graduated according to work done, ranging from 800 calories for dependents to 1900 for war-workers.

All who had the opportunity could supplement these rations from garden plots or by purchases in the free market, where prices were high. Some of these free markets were operated by the government. Prices for the two markets showed fantastic differences, viz., butter under the rations \$2.17 per kilo (about two pounds) compared with \$66 per kilo in the free market; beef \$1.17 under ration and \$33 free; sugar 46 cents per kilo rationed and \$75 free; black bread 8 cents rationed and \$12.50 in free market. This was at the time the dollar was exchanged for 12 rubles.

As the German armies were driven out of soviet territory and the red army advanced into other areas, the food supply was gradually increased. Planting in the U.S.S.R. proper, as well as in adjoining areas, was increased. The gains were slow, however, because of the lack of machines, animals, fertilizers and seeds. Available statistics for 1945 and 1946 indicated that in 1945 about 70% of the prewar acreage had been planted to crops in invaded areas. The official plans for 1945 called for increases in grains, indicating that the soviet government was planning to bring grain production up to the prewar level as quickly as possible, while beets and cotton were to be increased slowly. Considering the low levels of consumption still existing, it seemed unlikely that soviet food production would be back to the prewar level until two or three years later, and that export surpluses would be small for at least five years. Some shipments of grain were made in 1945 and 1946, but these were not used domestically. With the growing population, greater industrialization and demand for better living by the people, it appeared unlikely that the soviet union would become an important factor in world trade except as exports were needed to get exchange to buy scarce raw materials. The extent to which the nation might be self-sufficient for industrial development was as yet unknown.

Asia.—War was well under way in the far east during the first year of the decade, particularly in China. At first the invasion of China by the Japanese did not affect agricultural production as might be expected. China as a whole was always short of food supplies in some areas, as floods, droughts or other disasters destroyed crops. Famines and acute shortages were common because of the lack of adequate transportation facilities to move the surpluses of one area to the areas of shortage. In the 22 provinces for which scarcity reports were available, a crop of wheat larger than that of the United States was produced as well as twice as much rice and immense amounts of other crops for which no reports were available. Most of the immense population subsisted on what could be grown locally. As the war progressed, crop failures and continued military requisitioning by the invaders aggravated shortages. Free China made vigorous efforts to maintain production by distributing seeds and other materials, but these aids touched only a small part of the farm population. Gradually the total food production of China fell below that of the prewar years. Supplies shipped in by air "over the hump" from India could not be large. Military supplies were so important that until after the surrender of Japan the amount of agricultural supplies shipped was small. While the total of lend-lease aid to China exceeded \$1,335,-000,000, very little of this amount was for agricultural improvement. Lend-lease aid was continued to China after it had been officially terminated to other countries. An increase of imports in 1946 was expected if stocks could be found in the far east.

A long-time improvement of agriculture was undertaken by the national government. Agricultural experts from the United States and Britain advised the small but growing body of Chinese trained in agricultural science. A broad plan of agricultural education and extension was planned. Progress depended upon the return of peace and the development of transportation facilities—the greatest single need of China.

India.-Perpetually in short supply of food, India had been on the verge of famine before 1937. With the steady growth of population, the outlook was dark even before World War II brought new troubles in the form of the loss of the small quantities of imports which were of vital importance to the larger cities. While only about 3% of the total grain supply was imported, the total was so large that it was of considerable importance. When the Japanese cut off the rice supplies in southeastern Asia, the government of India began a program to increase food production by devoting more area to food crops. About 5,000,000 ac. were diverted from cotton to millet and about 1,000,000 ac. from jute to rice. Double cropping increased the food area by about 3,500,000 ac. Total supplies were not sufficient to maintain prewar consumption even at the low levels of that period. The constant pressure of increasing population kept production at the maximum of the ability of the people under existing methods. Any increase had to come from a radical change in agricultural practices or from some increase in industrialization to make products that could be exchanged for imported foodstuffs. The agricultural problems of India were unique in the world's agriculture and were a challenge to the scientists and statesmen alike. The war uncovered no promising solution except possibly the hope that a new form of selfgovernment might show the way toward improvement.

Japan.—Japan imported about 20% of its food supply in prewar years. The excuse for the invasion of Asia was the need of more land. Until 1944, the Japanese homeland got supplies from Manchuria and China to meet the requirements for her armies which did not live off the countries they had invaded. There was no serious food shortage until near the time of surrender, when shipping became limited. By 1945, the domestic supply was about 22% below prewar, and population had continued to increase. Foreign sources were cut off, and arrangements for trade were needed to provide for the future. After V-J day, U.S. military government co-operated with the local governments to open such trade channels. American cotton began to arrive in Japan early in 1946, and the textile mills reopened. Shortage of coal, however, delayed the complete reopening of industries. For future food supplies Japan looked to China, Manchuria and Indo-China, where there was sufficient surplus production to meet her

The great area of southeastern Asia where rice is the principal agricultural product was still producing below the prewar level in 1946. Small quantities of rice were available for export. Sugar shipments from Java were still small in mid-1946 because of political disturbances. Burma had small prospect of rice exports in 1946, although more than 3,250,000 tons had been exported on the average in 1935-40. The principal effect of the war in the southeastern Asia area was the disturbance of the normal marketing channels. Siam and Malaya reported the same shrinkage in the rice crop as did the neighbouring countries. All of these tropical countries with their large populations were showing their power to recover quickly in 1945 and 1946.

The permanent destruction by war was relatively small. (See Agricultural Research Administration; Census Data, U.S.; Chemurgy; Commodity Credit Corporation; Famines; Fertilizers; Horticulture; Irrigation; Law; Livestock; Meteorology; Price Administration, Office of; Prices; Soil Erosion and Soil Conservation; United Nations Relief and Rehabilitation Administration; Vegetables, etc.; also under principal agricultural products.) Air Conditioning

Although air conditioning applications had started about 1912, they were primarily of the industrial type as used in textile mills, until the introduction of comfort air conditioning in theatres about 1925. The application of air conditioning to small commercial establishments was very limited until about 1932.

The relative lateness of development of air conditioning for comfort as contrasted with air conditioning for industry may be explained by a number of factors such as the need for suitable refrigerants, the need for compact, lightweight, inexpensive equipment, a more difficult economic justification and the need for adequate distribution facilities.

The introduction about 1932 of the refrigerant dichlorodifluoromethane, "Freon-12," nontoxic and noninflammable, permitted the development of direct expansion systems in place of indirect systems which had previously been required for safe operation. This eliminated the necessity of water chillers, water pumps, spray chambers and expensive machinery rooms for the small commercial type of applications. It also permitted better over-all efficiency, lower operating cost, and lower maintenance cost.

Installations of air conditioning in 1937 were at least 700% of those in 1932. During the remainder of the decade 1937–46, installations levelled at a rate somewhat lower than the 1937 peak. At least 60% of all air-conditioning systems in operation by the end of 1941 were installed in the five-year period starting in 1937. Installations after 1941 were at a lower rate because of World War II.

Estimates compiled by Edison Electric institute for territories served by 150 electric utilities in the U.S. indicated a total of 81,978 installations at the end of 1941 (21,673 residential, 47,650 commercial, 4,759 industrial, 7,896 miscellaneous). Bureau of census statistics of shipments for 1940 and 1944 showed components of air conditioning systems and self-contained air conditioners in reasonable detail. Statistics for other years were not detailed enough to be of much value.

Room air conditioners of the self-contained air-cooled type increased from a negligible quantity to 19,205 in 1940 billed by manufacturers at \$3,438,775. There was no manufacture during the war years. Commercial air conditioners of the self-contained type introduced in 1937 increased to 5,880 in 1940, billed by manufacturers at \$4,466,926. Although production continued during World War II for essential applications, the rate was less until 1945.

Equipment.—The basic components of air conditioning systems, such as compressors, condensers, air conditioners and controls were simplified and made more efficient and reliable in operation during the decade 1937-46. In

addition, several new types of air conditioners and air conditioning systems were developed.

Reciprocating type refrigerant compressors, used in small and intermediate size air conditioning systems, were changed in many respects during the decade. Maximum speeds were increased from a range of 400 to 600 r.p.m. in 1937 to a range of 900 to 1,720 r.p.m. in 1946, and a few applications were made at substantially higher speeds. There was an extension in the use of multi-cylinder compressors of line, V, W and radial type, freer of vibration and more compact than the older types. The older designs which had suction and discharge valves in the piston were supplemented by designs having these valves in a valve plate at the top of the cylinder, permitting smaller clearance volume with lower operating cost and better accessibility for maintenance. Several types of modulating devices were developed to permit the operation of compressors under partial load conditions.

Centrifugal refrigerant compressors, used in the larger air conditioning systems (75 to 1,500 h.p. range), were also greatly improved in efficiency and reliability. The original designs were developed in Germany, but by 1946 the greatest number of manufacturers and the greatest amount of production was in the U.S. Switzerland, Germany and Japan were the only other countries where this type of equipment had been produced.

Condensers of air and water and evaporative types improved in performance, but did not change in general type. Water-cooled condensers were made in special alloys, such as copper-nickel, aluminum alloys and bronze for marine applications, using sea water for cooling.

Air conditioners of the central plant type, with spray chambers or heat transfer coils or a combination, changed little in general character. Room air conditioners of the self-contained type, on the other hand, changed radically. Up to 1937 the few that were sold utilized water-cooled condensing units which required water piping and water drain connections. Later, air-cooled types were introduced, mounted in or in front of a window, permitting the discharge of heat extracted from the room to the outside air, and the evaporation of moisture extracted from the room air into the outside air. The introduction of these types greatly simplified installation problems, reduced the cost and broadened the market.

Air conditioners of the self-contained type used principally in commercial applications were also developed and introduced about 1937. These units, originally of three h.p., were extended in size from one to 25 h.p. They were complete air conditioners with self-contained condensing units requiring only connections for water, electric wiring, water condensate, drain, and in some cases air ducts for air delivery. These reduced application and installation costs.

Two types suitable for air conditioning multi-room buildings, such as hotels and office buildings, were also developed and introduced. Both utilized individual room air conditioners of the cabinet type or built into an enclosure under the window of a room, and a central plant refrigerating system for refrigerating cold water circulated in pipes from a basement or roof location to the individual room air conditioners. In the first of these types an electric motor was used in the room air conditioner to circulate air over the cooling coils, and ventilation air was drawn through an opening in the wall or through a separate ventilation air duct. In the second type, a primary air conditioner was located in the machinery room to condition the ventilation air, which was supplied under relatively high pressure (of the order of six in. water gauge)

to an air nozzle in the room air conditioner. The latter induced the secondary flow of air from the room over the cooling coils.

Railway air conditioning systems were extensively developed during the decade 1937–46 in two main types, the reciprocating compressor type and the steam jet type. The latter, using steam from the locomotive, found widespread application, but later decreased in relative importance, partly because of maintenance problems when a cooling tower was used for condensing the steam. The reciprocating compressor types, in contrast, used air-cooled condensers and appeared to be gaining in relative importance. The drive preferred was electrical, in which electricity was generated from the axle, but mechanical drives from the axle and gas engine drive were also used.

Steam jet and absorption types of refrigerating systems were developed and used in commercial and industrial systems where central station steam lines or waste steam in processes were available. However, in general, these systems could only be justified where part of the cost of the steam required was absorbed by requirements for building heating, manufacturing processes, etc.

Applications.—Comfort air conditioning, which got its start in large theatres about 1925, was extensively applied in a variety of other applications during the decade 1937-46. Commercial establishments using air conditioning extensively included department stores, five-and-ten-cent stores, small stores, restaurants, amusement places having eating facilities, multiroom buildings, theatres, passenger cars, busses, passenger ships and aeroplanes. Residential applications also started during this period.

Industrial air conditioning likewise received great impetus during the decade because of production requirements brought on by World War II. In addition, special forms of air conditioning were used for strictly wartime applications. Industrial air conditioning was used in the storage and processing of materials, in precision manufacturing, in laboratories, in testing, and for work efficiency, health, comfort and safety for personnel in manufacturing plants. Air conditioning was particularly extensive in the very large windowless blackout type buildings built during the war for aeroplane manufacture, particularly in the U.S. It was also extensively used for engine, supercharger and intercooler testing, for refrigeration of wind tunnels used in testing aeroplanes and to simulate flight conditions for the testing of matériel and personnel. The latter application included development of stratosphere chambers to simulate high altitude conditions.

Military requirements dictated the extensive use of air conditioning for bomb sight installation, repair and calibration; special buildings for celestial training, Link trainer buildings; for the storage of wool flying suits; in parachute drying and storage; in airport control towers; aeroplane engine testing buildings; photographic development rooms and mobile units; in radar rooms, powder magazines, ready rooms for aviators, and other special applications aboard ships, also in armament, instrument inspection and adjustment, in armament fire control buildings, plotting rooms, operating rooms and convalescent rooms in military hospitals, hospital ships and hospital cars and portable food refrigeration units.

Distribution.—Approximately 85% to 90% of all air conditioning equipment in 1946 was installed in the U.S. The balance had been applied principally in Central and South American countries, India, China, the East Indies, Cuba, Mexico, Canada, and to a limited degree in France,

Germany, Italy, Belgium, Great Britain and others.

The large types of comfort air conditioning systems and most of the industrial systems had been sold direct by the larger manufacturers and by general contractors. The small commercial type systems were sold principally through distributors and dealers, most of whom had entered this business after 1937.

Many of these were exclusive air conditioning distributors; others combined this business with commercial refrigeration, residential heating, residential insulation and other types of businesses.

Standards.—The rapid growth of the air conditioning industry resulted in the development of a number of standards during the decade covering application, installation, rating and testing and safety requirements. Joint committees for rating commercial and industrial refrigerating equipment, sponsored by the American Society of Refrigerating Engineers, developed a series of rating and testing codes.

The National Fire Protection association developed a code on air conditioning, published by the National Board of Fire Underwriters as pamphlet No. 90.

The American Standards association developed project B-9 "Safety Code for Mechanical Refrigeration," including refrigeration in air conditioning. Minimum equipment standards were also developed by other groups such as the Air Conditioning & Refrigeration Machinery association and the division of trade standards of the U.S. department of commerce.

Airports and Flying Fields

The wide variety of types of aviation activities during the decade 1937–46—scheduled air transport operation, manufacturing and testing, military and naval combat flying and training, charter operations and personal flying and training—each had its own special requirements and standards of safety which were reflected in the aircraft and consequently in the airports designed to accommodate the particular activity.

By 1946, scheduled air transportation was using aircraft twice as heavy as those in use in 1937. Still heavier aircraft were yet to come, so that airport progress had to be measured in weight capacity as well as landing field size. The story of airports for the decade was that of trying to catch up with the widespread increase in use of air craft and their growth in speed and weight.

U.S. Airports.—In 1937, there were 2,299 U.S. airports recorded by the bureau of air commerce. Approximately 75 were owned and operated by either the army or navy, and the remainder were civil facilities.

About 10% of the total was used as terminals for the air lines and the remainder served the needs of personal flying.

At the beginning of the federal relief programs in 1933, public airport improvement or construction projects had been made eligible for federal assistance; through these programs a serious start was made to provide the facilities required by the expansion of the air transportation system and the improvements necessary to accommodate the transport aircraft coming into widespread use. Federal assistance to airport construction took the form of a labour contribution with the sponsor supplying the funds necessary for the materials and equipment.

Because of the national importance of uniform standards of design and construction to such a large program, the bureau of air commerce was made responsible for the approval of all airport improvement projects receiving federal aid. It was during this period that the bureau began the compilation of a national plan or outline for airport construction in the U.S. The purpose of this plan was to provide a correlated pattern of airports based on the requirements of civil flying, air transportation and national defense. The latter item was becoming increasingly important because of the small number of permanent military and naval airfields and the growing realization of the predominant part that air power would play in war.

Future aircrast, both civil and military, were put into the design stage at the beginning of this period, and it was becoming clear that the airports which were being built through the relies programs would not be adequate.

In 1938 the Civil Aeronautics authority (CAA) was created by congress. This act brought together into one organization the various agencies of the federal government which had to do with the encouragement and regulation of civil aviation. In the following year, several proposals were made in congress for specific legislation authorizing direct federal assistance to public agencies sponsoring airport improvement or construction. During this two-year period, 1937–39, the total number of airports recorded by the CAA decreased from 2,299 to 2,280. However, through the assistance of the Work Projects administration the over-all quality of the airports which remained available was improved.

International developments began to increase the urgency of airport development. The value of products of the aircraft industry in 1937 was \$114,092,601, of which \$39,404,469 represented the value of exported products; in 1939 the total value was \$247,904,863, of which the export proportion was \$117,807,082. In two years the volume of aircraft manufacturing had doubled with a corresponding effect on the use of airports as these aircraft were tested, flown to various destinations and placed in use.

Military and naval aviation received their first small authorizations for increased size and the implications of the future were becoming clearer. At the beginning of 1940, planning conferences were held between military and civil aviation officials to consider the most effective ways of expediting the airport construction necessary for the expanded military air forces. Because of the small

La Guardia field, New York city airport at North Beach, opened in Oct. 1939. Equipped with a 6,000 ft. runway, the airport was built at a cost of \$40,000,000

number of permanent military and naval air installations, civil airports constituted the base for the expansion of the service installations. Expansion and improvement of the civil airports would also have the effect of providing improvements badly needed for the expansion of air transport operations. Accordingly, it was determined to undertake a co-operative program of airport construction with the CAA providing the funds for those improvements which could be justified from the standpoint of civil aviation, and the military and naval services supplementing these funds for additional improvements to civil airports and, of course, constructing their own facilities where no future civil use was evident.

This program was accepted by the U.S. congress, and the first appropriation of federal funds in the amount of \$40,000,000 was made available to the CAA in Oct. 1940. The projects to be undertaken initially were selected and approved by the war and navy departments, and the first construction was begun in Dec. 1940.

The War Years.—As might be expected under conditions of war, U.S. civil flying other than scheduled air transport was extremely limited during World War II. At the outset of war many private aircraft were purchased by the government for pilot training or routine use by the army or navy. The number of transport aircraft in operation was reduced by requisition and purchase by the government from 453 in 1941 to 254 in 1942, and some certificated air routes were suspended for the dura-

tion of the war. The types of military and naval aircraft and kinds of operations became many and varied, each with its own special airport requirements. Expansion of the army and navy air forces immediately prior to and following the entry of the U.S. into the war required a great acceleration in the rate of airport construction.

The number of aircraft produced in 1940 was more than twice that of 1939, and the 1941 rate again was more than twice that of 1940. These were almost all military aircraft which had to be test flown and delivered to their destinations either in the U.S. or other parts of the world. Most of these activities took place on existing civil airports, and the ferrying of the aircraft was channelled over the civil airways system with the result that the airports began to receive extremely heavy traffic both in plane movements and in increased aircraft weight.

While the war activities required that airport construction be greatly accelerated, its principal effect was shown in the design of the fields themselves from layout to pavement load capacity. Increased traffic at major airports caused apparent design deficiencies in taxiways, apron sizes and runway layouts which limited the capacity of the port in aircraft movements; in addition, much of the paving which had been designed to support gross loads of 15,000 to 20,000 lb. with unlimited use, or 30,000 to 40,000 lb. with restricted use, began to fail.

The standard gross weight of the Douglas DC-3, which was used almost exclusively by U.S. air lines before and during World War II, was 25,200 lb. By 1942, training activities and transport and cargo operations were being conducted with aircraft weighing three times as much as

Northwest field, U.S. base on Guam for B-29 superfortresses, was put in operation June 1, 1945. From here the big planes took off to bomb Japan. The 8,500-ft. runway and the more than 200 hardstands were constructed of asphaltic concrete. Ten battalions of U.S. aviation engineers and seabees built the field in three months

a DC-3, and it was only a short time later that the very heavy bombers began to appear, operating under gross loads in excess of 100,000 lb.

Apart from the production of aircraft, the principal flying activity in the U.S. during the war period was the training of pilots and crews for action overseas. This alone was a prodigious undertaking, requiring not only the utilization of every suitable airport, but also the construction of hundreds of additional facilities, each group particularly designed for the special activities involved.

The flight training programs of the U.S. armed services faced a problem of high production with the maintenance of a high standard of quality and involved not only pilots but also navigators, bombardiers, flight engineers and gunners.

Airports for light aircraft had to be provided near the

colleges which were the centres for student traming, the first step in the air training program, where the student received 10 to 15 hr. of light plane flight time. Primary, basic and advanced training stations all had to be supplied with airports increasing in size and facilities as the training became more complex and the aircraft approached combat types. Training in flight as distinct from flight training had to be provided for other specialized airmen such as navigators, bombardiers and gunners, and the schools where they were trained had to be served by airports at the main base and auxiliary bases. Airports for gunnery schools, bombardment ranges and many other specialized uses had to be developed either through the CAA program or by direct army or navy construc-

In the final stage of training, the various crew members were brought together and trained as a unit in the type of aircraft they would use in combat. Thus, all types of aircraft from light artillery reconnaissance planes to superfortresses were flown extensively to and

from airports in the U.S., and adequate facilities for such operations had to be provided.

The need for special supplies, equipment and expert personnel at the many battlefronts all over the world was fulfilled by stepping up the transport services of the army and the navy. Some of these services were operated by several air lines under contract to the army and the navy while others were conducted directly by the armed forces. Vast amounts of cargo were handled by these operations, and the technique of cargo transport was greatly improved. Because of the nature of these operations, requiring scheduled operations over main and branch lines of supply, the airport and building requirements for cargo and freight hauling by air became apparent.

While all airport construction during this period was essentially for war purposes, the fundamental principle of the CAA defense airport construction program was to provide war facilities capable of conversion to civil uses in peacetime. This program, while not large, compared to many war expenditures, embraced more than 500 airports and resulted in an expenditure only slightly under \$400,

ooo,ooo in federal construction cost. In this program, municipalities were required to furnish the site, clear obstructions and provide utilities and access roads; the federal construction was limited to improvement of the site, and no CAA funds were used for airport buildings. Problems encountered under this program in the location of suitable sites, conflicts with existing airports and air traffic patterns and objections of surrounding property owners to airport establishment all pointed clearly to the necessity of emphasizing the importance of the community planning of airports if the expected postwar increase in civil flying was to be obtained.

The volume of aircraft operations and the development of specialized types of aircraft for specific tasks all contributed to the realization that only in lightly populated areas and smaller cities could all types of flying be accommodated on one airport without creating hazardous flying conditions. Faced by these problems, many of the larger communities in 1944 and 1945 began the studies necessary to provide the basis for development of a regional plan for airports. Such undertakings were complicated by the many types of political subdivisions in the major metropolitan areas, each having, in many cases, the authority to construct and operate public airports. Minneapolis and St. Paul, Minn., were the first to recognize the potential dangers in permitting uncontrolled airport establishment in a metropolitan area and to take effective measures to control such development.

In 1943 the legislature of the state of Minnesota authorized any two contiguous cities of the first class to establish a metropolitan airport commission which could acquire and control all airports and air-navigation facilities within the area specified. In addition, the commission could tax and expend the funds so acquired for the acquisition, maintenance, operation and construction of airports in the area, including necessary air rights over private and public property and the planning, investigations and studies essential to its operations. Thus the metropolitan area was equipped to control the construction of airports and work such developments into the community plan. In addition, the airport plans could be correlated with other plans for highway, road and street improvement. Finally, and most important, the commission through its power to raise funds by taxation and borrowing, was in a position to effectuate its program independently.

Early in 1944, the U.S. house of representatives requested the CAA to conduct a survey and prepare a report on "the need for a system of airports and landing areas throughout the United States," together with such recommendations for legislation as may be needed. The report requested was submitted in Nov. 1944 and early in 1945, after various bills following the legislative recommendation of the CAA had been submitted to both houses of congress, hearings were held on proposed legislation authorizing federal aid in the development of public airports along the lines of the successful federal aid highway program.

The Postwar Period.—The end of the war in Europe and later the surrender of Japan in the Pacific resulted in the elimination of most of the restrictions on U.S. civil flying which had been in effect after 1942. Resumption of private flying, with the return of many veterans and the sale of war surplus aircraft, encouraged the establishment of new airports and the reopening of many small ones. During the first six months of 1946, the increase in the number of this type of facility amounted to 16%.

In April 1946, congress approved a program of direct federal aid for the construction or improvement of public

airports, and it was expected that this assistance would supply the impetus necessary to obtain the airports necessary for vast expansion of civil flying.

The Federal Airport act authorized total appropriations amounting to \$500,000,000. The appropriation for any one fiscal year might not exceed \$100,000,000. Of the funds appropriated under this authorizing legislation 5% was to be retained by the CAA for the expense of planning and administering the airport construction program. The remaining 95% was divided into two funds. One, amounting to three-fourths of the 95%, was to be apportioned among the states in proportion to their population and area, the other was a discretionary fund to be allotted to specific projects which the administrator of CAA deemed most appropriate for carrying out the national airport plan. The act further authorized appropriations totalling \$20,000,000 for airport construction in Alaska, Hawaii and Puerto Rico, of which 50% was to be used in Alaska and 25% each in Hawaii and Puerto Rico.

In general, the act authorized the use of funds appropriated for land and easements in air space, for airport construction including the removal of hazards, and for the construction of airport buildings except hangars. Other provisions set the proportion of federal participation in the various items of work, classes of projects and locations of the projects. Some states also appropriated funds with which to assist public sponsors in the state in meeting the basic federal participation ratio of 50% to 50%. That this assistance would be necessary in maintaining adequate airport capacity for the expansion of both scheduled and non-scheduled flying was forecast by the rapidity with which the air line operators put into service larger aircraft such as the Douglas DC-4 and DC-6, Lockheed Constellation and Boeing Stratoliner, having gross weights in the 60,000 to 80,000 lb. range.

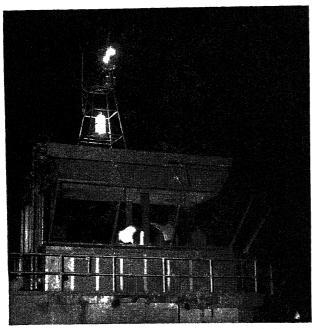

Many of the airports used by aircraft of this type and weight had their runways, taxiways and aprons improved during the war sufficiently to withstand the gross loads. However, there still remained a number of points generating sufficient traffic to warrant large aircraft service with airports insufficiently developed to handle these planes; a heavy proportion of civil airports serving the major cities could not stand frequent use by aircraft of the Lockheed Constitution, Douglas Globemaster, Consolidated CV-37 and Boeing Stratocruiser type, having gross weights between 130,000–320,000 lb.

The CAA continued to classify airports according to the effective lengths of the area available for take-off or landing. Class 1 airports had to have, at sea level, a usable landing strip of from 1,800 ft. to 2,499 ft. in length; class 2 from 2,500 ft. to 3,499 ft.; class 3 from 3,500 ft. to 4,499 ft.; and class 4 from 4,500 ft. upward.

There follows a comparison of the number of airports in the U.S. by classification for the periods discussed previously:

	J an. 1, 1939	Dec. 1, 1945	July 1, 1946
Class 1	1,693	1,550	1,797
Class 2	424	1,054	1,178
Class 3	57	479	488
Class 4		834	843
Total	2,174	3,917	4,306

Other Countries.—At the outbreak of World War II, all civil aerodromes in the countries involved were, for practical purposes, taken over for military use; civil flying was drastically reduced and controlled for the purpose of the war. Great programs of aerodrome building were introduced by all the belligerent countries. In Great Britain, where there were 150 aerodromes in 1939, there were approximately 600 when the war ended. The same degree of increase took place in almost every other European country belonging to or controlled by the major powers.

In 1937 and up to 1939 and 1940, aerodromes were generally grass-surfaced, or had a sandy or other natural surface according to the part of the world where the aerodrome was situated. Soon after the outbreak of war, the increase in size and weight of bomber aircraft and the need to be able to operate in all kinds of weather brought about the introduction of hard runways; this was a most important change in aerodrome layout. These runways were of concrete or some other form of hard surface, and were laid out in strips in two, three or more directions on the aerodrome according to the general meteorological conditions of the place. Up to 1939, a runway of 800 to 1,000 yd. on a grass-surfaced aerodrome was ordinarily sufficient; by the end of the war aerodromes used by heavy bombers had hard runways of 2,000 yd. for the main runways and only slightly shorter for the others. By 1946, on the main great terminal aerodromes being built in Great Britain and France, the principal runways were planned to be 3,000, 4,000 or 5,000 yd. long and the other runways 2,000 or 3,000 yd. A major problem regarding runways was the pattern in which they should be laid out. In 1944, there were two schools of thought: one favoured a series of parallel runways in perhaps three different directions which together built up two or more triangles, while the other preferred what was called the tangential system, in which the aerodrome buildings were situated roughly in the centre of a circle from which the runways were laid

out as tangents. The number of runways which could be built on either system depended upon the area of ground available and the limit to the cost incurred. The choice between these two methods was guided by the meteorological conditions of the site; the former was the better where weather would be bad for a large part of the year and the latter more suitable where almost continuous good and clear weather could be expected.

World War II brought about rapid development in radio and radar aids to air navigation and in the homing and safe landing of aircraft in bad weather and low visibility. This development also necessitated very long and wide, hard runways in the adaptation of navigational aids to civil flying. The Provisional International Civil Aviation organization drew up the following table of minimum lengths and widths of runways for various classes of civil aerodromes:

											٧	∕idth			
									Len	gth	Blind	Landing	Width Normal		
				CI	as	s			Feet	Metres	Feet	Metres	Feet	Metres	
Α									8,400	2,560	300	91	200	61	
В									7.000	2.134	250	76	200	61	
ō	i	·		·					5.900	1.798	200	61	150	46	
Ď									5.000	1.524	200	61	150	46	
Ē	·		-		-				4,200	1,280	200	61	150	46	
F	•	·	•		·				3.500	1.067	200	61	150	46	
Ġ		·		·	Ċ	Ċ			3.000	914	150	46	120	36.6	
	•	•	•	•	•	•	•		3,000	914	150	46	100	30.5	

Aerodrome costs rose steadily through the years 1937-46. In 1937, an expenditure of £500,000 was thought to be high for a first-class aerodrome, but in 1946 the estimates for big terminal aerodromes were £10,000,000, £25,000,000 and £50,000,000.

From a fairly simple civil engineering task in prewar years, the problem of planning and building a major airport became an engineering operation of the first magnitude. The acreage of land to be prepared in the case of the major airports rose from 750 or 1,000 ac. to 4,000 to 6,000 ac., and the numbers and sizes of aerodrome buildings, access roads and other aerodrome works increased in proportion.

During World War II, much use was made of steel meshing and steel plates which were joined together and laid on the ground to give a reasonably hard or resistant surface for landing. This device was specially used in the desert, on sea shores and on other sandy or soft surfaces; it was a cheap and efficient device, capable of development for the purpose of quickly establishing landing grounds for civil aircraft while a more permanent aerodrome was being constructed.

Many wartime aerodromes were only temporary and at the end of hostilities were either handed back to the owners of the land or were adapted, where suitable, for civil aviation. On the other hand, many of the aerodromes created for war purposes were even then looked upon as permanent, with the result that in all parts of the world. particularly in undeveloped countries, good aerodromes were provided which could be put to peaceful uses once the war was over. Ground work done by the air forces in Africa, India, Australia, the far east and the East Indies proved very valuable to civil aviation. A large number of these aerodromes were mere landing grounds and could only be very temporary because of the rapidity of the growth of vegetation in some districts, but the ground had been explored and the information gained of meteorological and other conditions in these places added to the store of knowledge on which to build for the future. Flying boat bases increased in number during the war years, and many of these became permanent. They did not present the same acute problem as the land bases in so far as the alighting areas were concerned; any sheltered area of water of sufficient size was a ready-made aero drome and the flying boat was in consequence much less restricted in its operations. Here again, the knowledge and experience gained established another line of development for postwar civil aviation.

None of the major airports for postwar Europe was completed in 1946. The biggest aerodromes in Europe were to be Heathrow (London airport) in England, Prestwick in Scotland, the Shannon airport in Ireland, Orly in France and an airport under construction at Lisbon. Close to the capital of every important country in Europe, Africa and Australia there was an aerodrome which before World War II was classed as A type, but which in postwar years might be classed as B or C. (See also Aviation, Civil; Aviation, Military; Municipal Government.)

(H. R. G.)

Air Races

In 1937, an Italian crew won the Istres-Paris race 3,800 mi. in 17 hr. 33 min. Frank W. Fuller won the U.S. Bendix transcontinental race (265 m.p.h.), and Rudy A. Kling the Thompson trophy race, chief event of the National Air races, at Cleveland (256.9 m.p.h.). After 1939, air races were discontinued in Europe for the duration of World War II and were resumed only on a very limited scale in 1946. Likewise, the National Air races (U.S.) were cancelled during the years 1940–45.

Jacqueline Cochran won the Bendix race in 1938, and the Thompson trophy went to Col. Roscoe Turner (283.42 m.p.h.), who repeated the feat in 1939. John Livingston won the Glenn H. Curtiss trophy at the 1939 Miami, Fla. meet (156.8 m.p.h.). The Bernarr Macfadden trophy race between New York city and Miami went to Max Constant in 1939 (5 hr. 44 min.) and to H. C. Rankin in 1940 (4 hr. 38 min.). The National Air races were resumed in 1946, with Paul Mantz winning the Bendix transcontinental race (435.6 m.p.h.) and Alvin Johnston taking the Thompson trophy (373.9 m.p.h.). (X.)

Air Raid Defense

Air raid defense or the protection of the civilian population caused both Allied and axis governments grave concern, so much so that in 1938 German, Swedish and British civil defense personnel were-working together in and around the dockyard towns on the Medway in England and witnessing exercises carried out with a view to saving life and dealing with casualties. The Germans provided much better shelter than the British, but Britain was facile princeps in its fire-fighting organization.

Before World War II, Sir John Anderson (later home secretary and minister of home security in Great Britain, 1939-40) lectured to the Imperial Defense college and to the staff colleges on air raid precautions. People with foresight began to think of the future safety of Great Britain and the commonwealth, and passive defense, air raid precautions or civil defense, the new baby of national defense services, was born. It was not at first a popular step and roused little public interest; during the first year of World War II, before the heavy bombing attacks on Great Britain began, quite a large percentage of citizens almost suggested scrapping the carefully-built civil defense organization. The cabinet and the home office meanwhile had deputed to a dozen regional commissioners the duty of co-ordinating civil defense, and these chosen deputies used that time as one of valuable training for fire fighters, rescue and decontamination squads, stretcher bearers, ambulance drivers and attendants, air raid wardens, repair parties, control and reporting personnel, etc. Preparation was made for dealing with the damage to water mains, gas, sewerage and electric light installations.

The shelter problem necessitated the appointment of a special regional commissioner in London. Generally speaking, adequate shelter was provided by local authorities, but some of the boroughs failed to provide proper shelter and ince the deep-shelter policy was turned down by the government as too costly to provide or, for a variety of reasons, an impossible undertaking, basements, surface shelters, underground tube station shelters, etc., were put under central control. Bunks were constructed and made available for distribution, priority of supply being given to the crowded East End boroughs. In recasting the shelter problem, the community was impressed with the need for dispersal as opposed to crowding thousands together in large communal shelters. Some of the bigger shelters were hit, and the casualties were heavy.

Civil defense in Britain was a community business on a territorial basis. Local government was mainly responsible for recruiting its members, acquiring its vehicles, establishing its depots and control centres and, largely, for its training and administration. Usually the town clerk, the chief local government official, was appointed official civil defense controller. In some cities and towns this duty was taken over by the chief constable.

Air raid defense from the civil viewpoint was concerned firstly with saving life, limb and suffering. Property generally came second, but industries, utility services and food supplies had high protection priorities, and it was the duty of the regional commissioners to ensure the minimum interference with production, war effort, health, morale and the education and upbringing of youth. Civil defense, when faced squarely, became a matter of common sense. Expert opinion helped in matters of shelter construction, protection against blast and splinter effect, fire fighting and the strengthening of buildings and special protection of such key points as power stations, pumping stations and communication centres. Water supplies for fire fighting during large-scale attacks were not at first up to requirements. The defect was overcome later by the building of an elaborate system of static water tanks and reservoirs.

British National Fire Service.—The National Fire service, built to start with on the peacetime fire brigade system, was enlarged by what was first called the Auxiliary Fire service, comprising thousands of men and women. The National Fire service built up a vast network of con-

Anderson air raid shelter installed in the bedroom of a private home in Glasgow, Scotland, during World War II

trols which extended and co-operated throughout Britain, and developed a new, highly-disciplined fire organization that was visited by the fire services of the United States, Canada and other Allied countries, whose representatives worked with the National Fire service for weeks at a time before going back to their own lands armed with experience of wartime fire fighting.

There were 1,725 fires in the city of London on Dec. 8-9, 1940, and 780 serious fires on Dec. 29, 1940, when the Guildhall was damaged and eight Wren churches were destroyed.

On March 19, 1941, there were 1,880 fires within the London region. The heaviest "fire blitz" occurred on the night of April 16, 1941, when there were no fewer than 2,251 fires, mainly in Chelsea, Westminster and Lambeth. On May 10, there were 2,154 fires in the centre and West End of London. The fire blitz then began in Liverpool. Following the London fire blitz of Dec. 1940, the government ordered compulsory fire fighting by civilians. Ellen Wilkinson (parliamentary secretary for the ministry of home security 1940–45) took over the general direction of the fire guard, and between the National Fire service and the wardens' service millions of men and women were trained and exercised until fire watching and fire fighting became part of air raid defense.

Civil Defense Services in Britain.—More than 1,000,000 people were enrolled in civil defense in Great Britain. In London alone, excluding the fire guard, nearly 250,000 people were enrolled to man the different services. The air raid wardens were the "front line soldiers" of the blitz; à very great proportion of them were volunteers or "part-timers." Wardens' work included a greater variety of duties than fell to the lot of any other civil defense service. The control room staff-operators, messengers, teleprinter girls, tally board and plotting clerks and the representatives of the heads of services-were in the charge of a selected deputy who supervised the reports from the wardens; the staff dissected them and dispatched the requisite aid. Members of the rescue party services were mainly builders' workmen, trained to lift steel girders and shift masonry and concrete blocks. They tunnelled under the debris of demolished buildings and cleared a way for the stretcher bearers. The rescue parties had their trucks fitted with standard equipment: jacks, levers, pulleys and tackle, wire and hemp rope, acetylene cutting plant, shores, sheer-legs, picks, shovels, axes and tools enough to satisfy most lifesaving and demolition requirements. The ambulance service was mostly run by women in civil defense. In London alone this ambulance service conveyed 93,524 casualties to hospitals and 609,783 inter-hospital patients. Other uses were made of this form of transport, and nearly 1,000,000 repair workers were carried for first aid to bombed buildings.

Closely associated with the ambulance service were the mobile hospital units of the field hospital type, usually with a crew of eight: medical officer, qualified hospital nurse, five assistants and man driver. Included in the casualty services were first-aid posts situated in places selected according to density of population and distance from hospitals. Hospitals, their size and capabilities were all worked into the civil defense plan, as were rest centres and mobile supporting columns, consisting of rescue parties and casualty units equipped to be rushed to any area which, through concentrated bombing, found its resources inadequate. An organization for housing the homeless was included in air raid defense and whether the bombed-out

people were to be accommodated for a very short time or permanently proved a very heavy commitment, especially in London, where well over 1,000,000 homes were hit and more than 250,000 destroyed. (E. R. G. R. E.)

United States.—The interest of the U.S. public in air raid defense followed the course of the war. At the time of Pearl Harbor, civilian defense had 3,516,600 volunteers and 7,031 defense committees. Two years later there were more than 12,000,000 registered, of whom 5,534,000 were assigned to duty in the protective services. By then the United States had the largest force of civilian volunteers ever formed for war service. Air raid defense included the army, the air force, Civil Air Patrol, state guards, state police, Red Cross and community welfare services. Each had a role and was prepared to carry out its part.

Long before Pearl Harbor, much had been done. In Sept. 1939, the governor of New Jersey appointed an emergency defense committee. In May 1940, Tennessee and Virginia organized the first state defense councils. By May 1, 1941, defense councils had been established in most of the states and in more than 1,000 communities. On May 20, 1941, the president, by executive order, established the Office of Civilian Defense.

When war was declared the framework was well under way. The pattern was that set up in England as a result of experiences there in 1940 and 1941. These demonstrated that the armed forces and the peacetime services of fire, police and medicine were not capable of meeting the impact of the new strategy of total war; that the existing services should be expanded with added equipment and personnel; new services should be added and the individual schooled to take care of himself and his home; and the nation should be mobilized to protect itself.

The OCD (headed by a director appointed by the president) with nine regional offices, was the national organization. Each state had its state defense council and many local councils, of which there were, at the peak, more than 12,000. Every community likely to be attacked organized one. The national government had no authority over the state or local councils. The OCD was a planning and co-ordinating body. The state and local defense councils were the operating units.

OCD set up the Civil Air Patrol, Forest Fire Fighters service, Facility Security program and civilian protection schools. Its training manuals and guidance on gas defense, blackout, dimout, shelters, camouflage, organization, communications, safety measures and the many other problems of civilian defense were followed by state and local councils. It became the research and advisory centre.

The army air force operated the Aircraft Warning service, with some 600,000 volunteers to warn communities of impending attack. To insure necessary uniformity, the army promulgated an air raid warning system and controlled practice blackouts. The local units had the true responsibility. Operating through a staff, air raid warden, auxiliary police, auxiliary fire, utility repair, road repair, emergency medical and related services and headed by a commander—the mayor, a well-known citizen, or the head of the police department—these people took their task seriously. They knew that if they failed in their mission there was little hope for their community. Each local unit was expected to be strong enough to handle any anticipated attack.

Every community was far short of the fire equipment necessary to handle effectively the fires resulting from even a small attack. To meet this, in Feb. 1942, congress appropriated \$57,000,000 for pumpers, hose and other equipment for communities in critical zones, and \$43,000,000 for

gas masks, helmets, arm bands, medical supplies and miscellaneous equipment for the individuals of the defense corps.

Neither Germany nor Japan was capable of bombing the United States during World War II. How well the civilian defense organization would have kept down the effect of any air raid attack was unknown. Some units performed creditably in local emergencies, which were, in some sense, tests of their efficiency. Experiences elsewhere pointed to many ways in which it might have been improved, yet it accomplished much. It stood out as the greatest example of U.S. mass mobilization, organization and training ever undertaken by volunteers. Communities found a way to unite by themselves for their own welfare. It gathered the people behind the war effort. (See also Electrical Industries; Incendiary Warfare; Municipal Government.)

Air Transport Command

Before the close of World War II the air transport command of the U.S. army air forces had become the largest agency for air transportation yet developed, and had demonstrated to the world a new principle—strategic air supply. In the beginning, the ATC was a tiny organization with a relatively limited mission. Established on May

U.S. officers boarding a giant Skymaster (C-54) plane at a West African base. The C-54 was in standard use by the air transport command during World War II for long range flights

29, 1941, as the air corps ferrying command, it was made responsible for ferrying aircraft for the British from U.S. factories to transfer points, and for transporting essential passengers and mail between the U.S. and the United Kingdom. Within a year, in answer to the demands of war, its duties were broadened to include delivery of aircraft to Allied forces wherever found and the operation of a world-wide air transportation system. By June 20, 1942, when the ferrying command became the air transport command, it had accomplished or supervised the delivery of 13,513 aircraft to final domestic destinations and 638 to final foreign destinations, and, largely through contract carriers, had transported 1,920 tons of passengers, cargo and mail. Brigadier General Robert Olds, the first commanding general of the command, was succeeded in April 1942, by Lieutenant General (then Colonel) Harold L. George, who continued in this capacity until Oct. 1946.

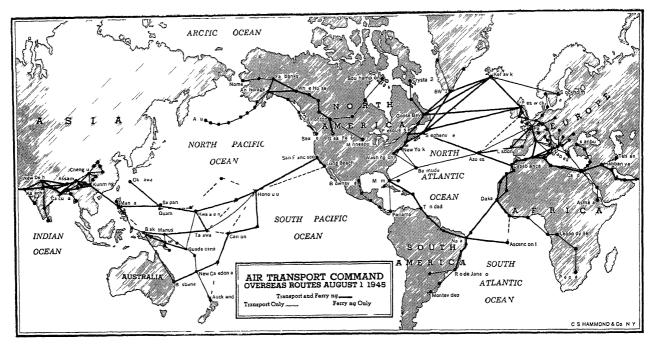

In Dec. 1942, ATC took over the hazardous job of flying the "Hump"—transporting supplies over the Himalayas from Assam, India, to China. Previously the greatest load carried to China in any one month had been 1,136.2 tons. ATC operations gradually enlarged this trickle into a heavy stream—2,278 tons in March 1943, 18,975 in July 1944, and finally the record total of 71,042 in July 1945. Meantime, ATC services elsewhere were expanding. As the Allies advanced on fortress Europe from North Africa and across the channel from Britain, ATC followed. In the Pacific, as the Japanese were forced back toward their home islands, ATC routes moved northward, until the main line no longer ran to Brisbane, Australia, Guadalcanal, or Saipan, but to Tokyo.

In addition to ferrying aircraft and operating regular transport services, the command from the time of its origin conducted a wide variety of special missions: for example, flying President Roosevelt to international conferences, and, within three weeks, transporting 25,799 Chinese troops, their equipment and pack animals into battle areas. After the surrender of Japan, ATC moved 23,456 occupation troops, 1,191 vehicles and a mass of supplies into Honshu, all in 16 days.

The year 1945 was mainly one of redeployment; in two special projects ATC moved 154,497 passengers from the Mediterranean and European theatres to the U.S. and supervised the homeward flight of 5,965 tactical aircraft which, counting crews, returned 84,614 additional men. Air evacuation, begun on a significant scale in 1943, reached the greatest volume in 1945, when the command carried a total of 212,819 patients, nearly two-thirds of them on international routes. In 1946 the command, sharply reduced in aircraft and personnel, shouldered its peacetime responsibilities of maintaining an air link with the occupation forces, providing certain scheduled services and special missions best handled by military rather than commercial carrier, and keeping in readiness a pool of highly experienced personnel and the nucleus of a worldwide air transport organization.

At its peak, the command had a strength of 41,705 officers, 167,496 enlisted personnel and 104,677 civilians. Its scheduled routes extended over more than 146,000 miles. Its aircraft numbered 3,705. By the close of hostilities, it had transported more than 4,000,000 persons over 8,500,000,000 passenger-miles. Its aircraft had flown more than 1,000,000,000 miles to accomplish a traffic movement of 2,702,864,509 ton-miles.

Alabama

Alabama, located in the east south central division of the United States, commonly called the 'Cotton state," was admitted to the union Dec 14, 1819, as the 22nd state. Area 51,609 sq mi, including 51,078 sq mi of land and 531 sq mi of water Population (1940) 2,832,961, 1944 estimate, 2,818 083 Of the 1940 population, there were 1,849,097 whites, 983,290 Negroes and 574 of other races, 2,821,004 native born whites and 11,957 foreign born In 1940, 30 2% of the population was urban and 69 8% rural The capital, Montgomery, had a 1940 population of 78,084; chief other cities were Birmingham (267,583) and Mobile (78,720).

In 1937 the prohibition system, in effect after 1915, was abolished and the system of local option by counties was adopted Twenty four of the 67 counties permitted the sale of hard liquors The traffic remained under the control of the state board

Chief officers of the state, 1937–38 were governor Bibb Graves, lieutenant governor, Thomas Knight (deceased), attorney general, A A Carmichael, auditor, C E McCall, secretary of state, Howell Turner, treasurer, John Bran don, superintendent of education, A H Collins, and commissioner of agriculture and industries, R J Goode

Elected for four years beginning Jan 16, 1939, were governor, Frank M Dixon, lieutenant governor, A A Carmichael, auditor, Howell Turner, secretary of state,

John Brandon treasurer, C E McCall, attorney general L J Lawson superintendent of education, A H Collins commissioner of agriculture and industries, J H Paterson An amendment to the constitution, July 1939, provided for election of legislators biennially

In the presidential election of 1940 the voting was Roosevelt 250 723 Willkie 42,184, Babson (Prohibitionist) 700, Browder (Communist) 509, Thomas (Socialist) 100

Chauncey Sparks (Dem) was elected governor Nov 3 1942 to succeed Frank M Dixon Eight of the nine con gressional representatives, all Democrats, were re elected The new representative, from the 9th district, defeated Luther Patrick, the incumbent, in the Democratic pri maries run off election in June Aside from Gov Sparks, the principal state officers elected in Nov 1942 were Handy C Ellis, lieutenant governor, Warren C Lusk treasurer, John Brandon, auditor, Howell Turner, secre tary of state, Joe N Poole, commissioner of agriculture and industries, and Elbert B Norton, superintendent of education (A B Mo, X)

Six amendments to the state constitution were proposed at the 1944 general election, four were ratified Incum bents of principal elective offices of the state government were Chauncey Sparks, governor, Handy C Ellis, lieu tenant governor, William N. McQueen, attorney general John Brandon, auditor, Joe N Poole, commissioner of agriculture and industries, Gordon Persons, chairman, Pub lic Service commission, Sibyl Pool, secretary of state, Wal ter C Lusk, treasurer, and Elbert B Norton, superintend ent of education Votes cast for presidential electors at the election of 1944 were as follows Democratic 198,918 Republican 44 540, Prohibition 1,081, and Socialist 190

The legislature met in regular session from May 1 to June 29, 1945, inclusive, introducing 993 bills, passing 437 acts and proposing 10 amendments to the state constitution 9 of which were not to be voted upon by the people until 1946. The defeated proposed constitutional amend ment voted upon on Oct. 2, 1945, proposing to change the disposition of the state income tax revenues, received

42,368 votes for and 75,308 votes against.

In 1946, the following were elected to the principal state offices, with terms beginning in Jan. 1947: James E. Folsom, governor, J. Clarence Inzer, lieutenant governor; Albert A. Carmichael, attorney general, Dan Thomas, state auditor; Haygood Paterson, commissioner of agriculture and industries; Sibyl Pool, secretary of state; John Brandon, state treasurer; Austin R. Meadows, state superintendent of education.

Alanbrooke, 1st Viscount (Alan Francis Brooke)

Viscount Alanbrooke (1883—), British peer and army officer, was born July 23, 1883, at Bagnères de Bigorre, France. Following completion of his studies at the Royal Military academy, Woolwich, he joined the field artillery, 1902. At the outbreak of World War I, he went to France with the B.E.F. and was a general staff officer of the royal artillery at the time of the Armistice, 1918. After the war, he joined the staff college, Camberley, and the imperial defense college and was commandant of the school of artillery, 1929—32. In 1939, he was named commander in chief of the anti-aircraft command.

As commander of the B.E.F.'s 2nd army corps in May 1940, he was one of the British military leaders responsible for the effective rear guard defense of the British forces that were evacuated from Dunkirk in May and June. Back in England in early June, he hastily reassembled and reorganized the vestigial British forces for the expected invasion and directed defense preparations. He was knighted for his achievements in Europe and on July 19, 1940, he succeeded Sir Edmund Ironside as commander in chief of British home forces.

On Nov. 18, 1941, he became chief of the British imperial general staff. In this capacity, he accompanied Churchill to the numerous conferences with Roosevelt and Stalin. He was made a field marshal in the king's New Year's honour list for 1944 and was awarded, that same year, the Order of Suvorov, first class, the soviet union's highest military decoration. He was named a baron in Aug. 1945 and on Jan. 1, 1946, he was created 1st Viscount Alanbrooke.

Alaska

Alaska, one of two duly constituted territories of the United States, was discovered by Vitus Bering and Alexei Chirikov in 1741. It was purchased by the U.S. from Russia in 1867 for \$7,200,000. This vast territory of 586,400 sq.mi. was for many years under the control and supervision of the U.S. army. It was given territorial status in 1912 with the passage by congress of the Organic act, which provided for a legislature of two houses and permitted the residents of the territory to elect some of their own officials.

During the decade 1937–46, great changes took place in Alaska. Whereas ten years before only a few aeroplanes were used in the territory, a network of established air lines, airfields and feeder routes had put Alaska on the air map of the world by the end of the decade. One could in 1946 travel from Point Barrow, the northernmost tip of the territory, to Juneau, the capital in the southeast archipelago, in one day—a distance of more than 1,000 mi. Ten years before, one trip a year to Barrow with an icebreaking boat was the only transportation possible to and from that outpost.

With the coming of World War II, Alaska's population leaped to more than twice the 1939 census figure of 72,524. Prior to 1940 and 1941, Alaska's military and naval establishments were virtually nonexistent. It had a garrison of only some 200 regular army infantry at Chilkoot barracks, near Haines. Before the end of the fiscal year June 30, 1941, however, federal expenditures of some \$70,000,000 had been authorized for Alaska's defense. Construction on navy bases at Sitka, Kodiak and Dutch Harbor and on army bases at Anchorage, Fairbanks, Nome and the Aleution chain were undertaken. This vast expenditure brought thousands of construction workers to the territory in addition to the military personnel. Many of these remained in the territory. The estimated population in 1946 was approximately 100,000.

World War II brought permanent improvements to Alaska in the form of fine airports, radio range stations and other aids to aerial navigation. It brought some 400 mi. of additional highway, particularly the 136-mi. Glenn highway from Palmer connecting the network of roads around Anchorage with the Richardson highway; that portion of the Alaska Military highway (the road through Canada to the U.S.) extending from Big Delta, 203 mi. southeastward to the Yukon territory boundary; and the so-called 72-mi. Tok cut-off connecting this highway with the Nabesna road.

From the very beginning of the war years, Alaska industry converted itself to war activity. The fishing industry, long the mainstay of Alaska's economic structure, operated in accordance with the salmon industry's consolidation plan under the direction of the secretary of the interior, which required the concentration of the industry in the more efficient plants in order to effect savings in manpower, equipment and critical materials, and to lessen the requirements of shipping facilities. As high as 75% of the salmon pack during the war years went directly to the armed forces.

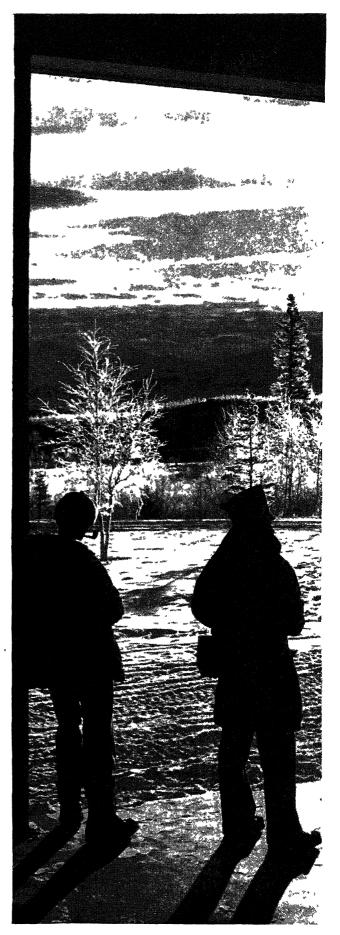

The mining program for the field seasons of the war years also was influenced by the needs of the U.S. war and navy departments. At the close of the fiscal year 1945, six projects relating to mineral commodities, for which there was an acute demand to meet war needs, were in progress. Possibilities for the development of petroleum projects were investigated at Katalla and Wide Bay in the summer of 1944 and along the Killik river, a tributary of the Colville river in northern Alaska.

Military activity in Alaska and the subsequent influx of labour necessary for the completion of military and naval installations resulted in a critical coal shortage during the winter of 1943-44. In co-operation with the Military Coal commission, the bureau of mines undertook to investigate the extensive coal deposits of Alaska and to prove by exploration the existence of the more extensive minable beds. As a result of this work, reserves adequate to supply the demands of the territory for many years were proven.

In the field of war finance activities the achievement of Alaska and its people was noteworthy. In the 1943 and 1944 war fund campaigns, Alaska established the highest record of any state or territory, attaining more than 175% of its quota. In the period from May 1, 1941, to Dec. 31, 1945, Alaska's population had purchased \$23,755,000 worth of "E" bonds. In addition, \$5,150,000 was invested in other forms of government bonds. It was significant also that from its census population of 72,524, Alaska had 5,309 of its men and women in either the armed forces or their auxiliaries, serving in every theatre of war and in most of the major combat engagements. To assist these returning service people, the 1946 special territorial legislature enacted a liberal law which provided that Alaska veterans would receive a cash bonus of \$10 for every month of service, or, two classes of loans: first, loans up to \$2.500 for educational, domestic and other purposes, and second, loans up to \$10,000 to purchase or build homes, acquire farms or other business property, or to finance mining, fishing and other enterprises.

While there were certain cutbacks in fish production during the war, Alaska produced approximately 50,000,000 cases of canned salmon during the decade, with an average

U.S. soldiers on leave at the McKinley park hotel, Alaska, during World War II. The hotel, built by the U.S. government in 1938 for tourists, was taken over by the U.S. army to provide a vacation spot for war department employees in Alaska as well as for soldiers on leave from duty in Alaska or the Aleutian Islands

price of from \$10 to \$12 per case. The halibut fishery yielded between 40,000,000 and 50,000,000 lb. annually during the decade. Shrimp, crab and clam production yielded additional millions to fish production.

Despite a drop in fur production during the war years, the average annual value of skins taken in Alaska was approximately \$2,000,000. This included mink, otter, fox, ermine and marten. Fur seal production in the Pribilofs, handled under international agreement, was suspended during the war, but during the three years preceding hostilities and in 1945–46 the estimated value of seal skins taken was \$1,000,000 a year. Fish and wildlife officials reported that, during the 1946 season, the seal herd which ten years before was almost extinct had been built up to more than 3,000,000 animals. Exceptionally high postwar prices encouraged the fur industry, and steps were taken to revive fur farming, which had been retarded during the war.

An event of outstanding importance in 1938 was the closing of the Copper River & Northwestern railroad, which had been built in 1908 from Cordova to Kennecott to ship ore from the Kennecott copper mine to the coast. It was built under the most difficult engineering conditions at a cost of \$24,000,000, and later became the basis for Rex Beach's novel *The Iron Trail*. Exhaustion of the rich copper ore deposits led to the closing of the railroad. Later Cordova, which had been largely dependent on the railroad and the copper mines, developed one of the outstanding clam fisheries in Alaska.

School enrolment steadily increased and 44 1 ural and 18 city schools had a total enrolment of more than 5,000 white pupils in 1946. Fourteen of the territory's high schools had been accredited, so that students completing the four-year course were eligible to enter various colleges and universities. The entire plant of the University of Alaska at College, near Fairbanks, was taken over by the army during World War II and served as a training centre for various army personnel. In addition to the white schools, the Alaska native service, under the department of the interior, maintained 119 day schools and three vocational high schools for Indian, Eskimo and Aleut children in 1946, with an enrolment of around 8,000. Total enrolment in all schools, both white and native, averaged around 13,000 annually over the decade 1937–46.

Communication service to the territory made great strides during the decade. Sept. 26, 1946, saw the opening of land line telephone service between southeast Alaska, interior and westward Alaska and continental U.S. for the first time. This was accomplished by the Alaska communications system, a branch of the U.S. army signal corps, laying a cable from Juneau, the capital, to Skagway, at the north end of the southeast Panhandle. At the latter point, connection was made with the line built by the army during the war years, running to Whitehorse in Yukon territory and thence along the Alaska Military highway to Edmonton, Canada, and on to the U.S. via private lines. New cables were in process of being laid in 1946 between other southeast Alaska towns-Petersburg, Wrangell and Ketchikan. Anchorage and Fairbanks previously had land line telephone connection to the states. Ten years before, the only communication possible was by signal corps radio and, seven years before, by radiophone. In addition to the army's Alaska communication system, covering all major points in the territory, the Alaska Aeronautics and Communications commission, territorially supported, provided

Mountains of Attu through which U.S. forces filed to attack Japanese after landing on the tiny Aleutian island May 11, 1943 radiophone service to most of the smaller places and extended an added service

to aeroplanes.

Population figures of the Oct. 1, 1939, census: 39,170 white, 15,576 Eskimo, 11,-283 Indian, 5,599 Aleuts, 262 Japanese, 633 other and unknown races; total, 72,524. Population of incorporated towns by 1939 census: Juneau, 5,729; Ketchikan, 4,695; Anchorage, 3,495; Fairbanks, 3,455; Sitka, 1,987; Nome, 1,559; Petersburg, 1,323; Wrangell, 1,162; Seward, 949; Cordova, 938; Kodiak, 864; Skagway, 634; Valdez, 529; Douglas, 522; Craig, 505; Klawock, 455; Seldovia, 410; Haines, 357, Unalaska, 298.

Governors of Alaska during the decade 1937-46 were: John W. Troy (May 27, 1937, to Dec. 6, 1939); Ernest Gruening (after Dec. 6, 1939). Secretaries of Alaska were: Edwin W.

Griffin (June 22, 1937, to Feb. 2, 1939); Edward I.. Bartlett (Feb. 2, 1939, to July 1, 1944); Llewellyn M. Williams (after July 1, 1944). Elected territorial officials were: Ralph J. Rivers, attorney general; Frank A. Boyle, auditor; Oscar G. Olson, treasurer; W. Leonard Smith, highway engineer; Walter P. Sharpe, commissioner of labour. Appointed territorial officials: Ben D. Steward, commissioner of mines; Dr. James Ryan, commissioner of education; George Gasser, commissioner of agriculture; Dr. C. Earl Albrecht, commissioner of health; Russell G. Maynard, director of public welfare; Robert E. Sheldon, director Unemployment Compensation commission. (See also WORLD WAR II.) (L. M. W.)

Albania

Albania is a nation in the western part of the Balkan peninsula bordering on the Adriatic. Area 10,631 sq.mi.; pop. (census 1930) 1,003,068; (estimate 1939) 1,063,000. Capital, Tirana. Chief cities (1930 census): Tirana (30,-806); Shkodër or Scutari (29,209); Korce or Kortcha (22,787); Elbasan (13,796); Vlonë or Valona (9,100). Religion: Mohammedans (688,280); Orthodox Christians (210,313); Roman Catholics (104,184).

The ten eventful years of 1937-46 witnessed the temporary eclipse of Albania as an independent nation and her restoration as one of the Balkan states under soviet Russia's influence. The country, which had proclaimed its independence from Turkey on Nov. 28, 1912, was ruled as a constitutional monarchy in 1937 by Ahmed Bey Zogu, who had been elected president of the Albanian republic

Italian Occupation.—On April 7, 1939 (Good Friday), Italian forces suddenly invaded Albania. King Zog was forced to flee, and the country received a new constitution, according to which it became a nominally independent kingdom under the crown of Italy. King Victor Emmanuel III, emperor of Ethiopia, became king of Albania; the principles of fascist life and administration were introduced officially as the foundation of Albanian civilization.

The following year in Albania was taken up with the construction of strategically important roads to the Greek and Yugoslav frontiers, fortification of the country and the storing of large military supplies. In Aug. 1940, the press in Albania and in Italy began a violent campaign against Greece, accusing the latter of oppressing the Albanian minority in the Greek Epirus and claiming the need to protect and liberate these Albanians. In pursuance of this policy, Italy on Oct. 28 suddenly presented an ultimatum to Greece and three hours later started to invade the country from Albania. Against all Italian expectations, the heroic Greek resistance forced the Italian armies not only to withdraw entirely from Greece, but to retreat into the interior of Albania. At the end of November the Greeks occupied the most important Italian military bases there, Kortcha in the north, the third largest town in Albania, situated in a well cultivated and prosperous area, and Argyrokastro in the south, the fifth largest town. From there the Greeks pressed forward toward the sea, conquered Porto Edda, named after Mussolini's oldest daughter, and pushed toward the great port of Valona and toward Elbasan in the centre of the country. The British

royal air force repeatedly bombarded Valona and the other large Albanian port, Durrës or Durazzo.

At the beginning of 1941 the Italian troops under strong Greek pressure were everywhere in retreat, and the Greek armies were in occupation of a large part of Albanian territory in the east and southeast of the country, where they restored the Albanian law as it had existed before the invasion of the country and its union with Italy. In the first months of 1941 the Greeks succeeded in holding all Italian attempts at a reconquest of the lost territory, and even expanded their hold on the country.

In March 1941, Premier Mussolini himself visited the Albanian front and assumed personal direction of the operations. Nevertheless, the Italian offensives all failed with very heavy losses. Neither, however, were the Greek forces strong enough to capture the long-assaulted Tepeleni on the central front and Valona on the sea. But the Albanian situation changed fundamentally through Germany's active participation in the war against Greece. On April 6, 1941, the German forces began active operations against Yugoslavia and Greece. By mid-April the Yugoslav army had surrendered, the Greeks were pushed far back and were unable to hold the Albanian front any longer. Under these conditions the Italians could reoccupy the parts of Albania evacuated by the Greeks, and on April 22 even cross the Greek frontier. The next day the Greek army in the Epirus surrendered to the advancing Germans. From that moment Albania came again under Italian administration, and fascist laws were reintroduced throughout the country.

Confusion After the Italian Surrender.—The Italian capitulation in 1943 threw Albania into a turmoil. The Allies had pledged repeatedly the restoration of a free Albania, and Prime Minister Winston Churchill reiterated this pledge in the house of commons on Nov. 4, 1943, promising an Albania "free from her Axis yoke and restored to her independence." He also said that British officers were co-operating with Albanian guerrillas.

There existed no Albanian government in exile, and Albania was not recognized officially as one of the United Nations. King Zog lived in exile in England, whence he later moved to Egypt.

The Germans promised the creation of a Great Albania at the expense of Yugoslavia and Greece, and insinuated that a victory of the United Nations might mean the division of Albania between Yugoslavia and Greece. But the Albanian Freedom movement continued throughout 1944 to fight the Germans. As in Yugoslavia and Greece there were different rival factions. The party of National Liberation with its "People's Liberation Army," under communist influence and the leadership of Enver Hoxha, a 36-year-old former schoolteacher, resembled the group led by Tito in Yugoslavia and the E.A.M. in Greece. The more conservative National Front (Balli Kombtar) was opposed to the first group, while the supporters of the exiled Zog formed a third faction under the leadership of Abbas Kupi.

The United Nations repeatedly appealed to the Albanians to unite against the Germans. On the fifth anniversary of the Italian invasion of Albania the United States state department reaffirmed the refusal to recognize the annexation of Albania and asked the Albanians to hasten the restoration of their country by uniting. In May 1944 deputy prime minister Clement R. Attlee disclosed in the house of commons that Great Britain had liaison officers in Albania trying to establish a united

front against the Germans and was sending arms and ammunition to the various guerrilla bands. During the summer of that year, battles developed in Albania between the Germans and Albanian patriots, while Allied intervention succeeded in preventing conflicts among the rival factions of the patriotic forces. In the fall, with the changing war situation in the Balkans, the German position in Albania weakened.

Liberation.—In Oct. 1944, British forces captured the port of Sarande in southwestern Albania, opposite the Greek island of Corfu, and on Nov. 18 Tirana, the capital of Albania, was liberated by Albanian patriots. A provisional government of the "People's Liberation Army" promised far-reaching social reforms, declared itself for full collaboration with Tito's Yugoslav regime, and insisted on the territorial integrity of Albania. Hoxha was proclaimed head of the government in addition to his posts as minister of war and commander in chief of the Albanian army. The Albanian leader, looking to Moscow for guidance, glorified Marshal Stalin's Russia and Marshal Tito's Yugoslavia as examples of true democracy.

The Albanian government's demand for a seat at the United Nations conference in San Francisco, Calif., transmitted to the world by the Russian and Yugoslav radios, was rejected. On May 8, 1945, an informal U.S. mission under John F. Jacobs entered Albania to survey conditions. On Aug. 1 an agreement was signed between the Albanian government and Col. D. R. Oakley Hill, chief of the United Nations Relief and Rehabilitation administration in Albania, according to which U.N.R.R.A. would furnish Albania with food, textiles, engineering equipment and medical and agricultural supplies to be distributed "without discrimination" by Albanian authorities. On Nov. 10, 1945, the U.S., Great Britain and Russia recognized the Albanian regime. Elections at the end of November confirmed the Hoxha regime.

The National Assembly, in which only the one governing party, renamed Democratic Front, was represented and no opposition was allowed, proclaimed Albania a republic in Jan. 1946. Throughout the state Russian influence became paramount. Col. Gen. Hoxha's chief adviser was the minister of information, M. Maleshova, ideological leader of the Albanian Communist party who had lived for 15 years in Russia and returned only during the war to his native land. Much was done for the upbuilding of the country during 1946; U.N.R.R.A. relief supplies enormously improved the economic situation and the state of public health. But civil liberties, though proclaimed on paper, ceased to exist. The Catholic element in the northern part of Albania and the Greeks in the south complained especially about systematic persecution. By maintaining a relatively large army and by controling the strategic island fortress of Sasseno, Albania came to occupy an important political position dominating the Adriatic sea.

In the latter part of 1946 diplomatic differences between Albania on the one side and the United States and Great Britain on the other side grew more serious. Bitter Albanian propaganda was directed against the two countries. As a result of the unfriendly attitude of the Albanian government Britain recalled its military mission. A Russian demand for the admission of Albania to the Paris conference on the Italian treaty in Aug. 1946 was opposed by the U.S. secretary of state, James F. Byrnes. Albania concluded a naval agreement with Yugoslavia on Sept. 10, 1946, and was reported to have heavily fortified, with Russian help, strategic points on the Adriatic coast. In Nov. 1946 the U.S. diplomatic mission at Tirana was withdrawn.

Alberta

Alberta, created on Sept. 1, 1905, is the most westerly of Canada's three prairie provinces, although consisting more of foothills and forests than prairies. Its area is 255,-285 sq.mi., 6,485 sq.mi. of which are water. Saskatchewan lies for 750 mi. along the east; the Northwest Territories extend 400 mi. across the north; British Columbia is along the west, where the boundary line is the eastern fringe of the Rocky mountains; 100 mi. of Montana is along the

Centres of population are Edmonton, the capital (1901 census, 4,176; 1941, 93,817; 1943, 131,050); Calgary, Lethbridge, Medicine Hat (1941 census: 88,904, 14,612, 10,571 respectively). There are many language groups in Alberta, but English predominates: German, Ukrainian and Scandinavian groups are next. Largest religious group in 1941 was the United Church of Canada, with the Roman Catholic Church a close second and the Church of England third. Twelve other religions were listed.

The population of the province increased from 731,605 in 1931 to 796,169 in 1941. Despite the shifts caused by World War II, the dominion bureau of statistics estimated growth to 826,000 by 1946; but population density in Alberta was still second lowest in Canada, with 3.2 persons per square mile as compared with the Prince Edward Island figure of 43.52 persons.

Lieutenant governors during the 1937-46 decade were

Lieutenant Col. P. C. H. Primrose (Sept. 10, 1936-March 20, 1937), John C. Bowen (from March 20, 1937). Premiers during the period were: William Aberhart (Sept. 3, 1935-May 23, 1943), E. C. Manning (from May 31, 1943).

THE CENTRE of interest during the 1937-46 decade was, for reason, the Social Credit provincial government, only one of its kind holding office anywhere. In 1935 it had swamped the United Farmers of Alberta by winning 56 of the 63 seats in the legislature; it retained office in the 1940 election, though dropping to 36 seats; but in 1944 it won 51 seats. Electoral confidence was maintained, despite repeated failures to produce the much promised social credit dividend, because both the Aberhart and the Manning (but most particularly the latter) governments were characterized by administration efficiency. Nevertheless,

both leaders made efforts to practise social credit doctrine. After working on the "\$25 a month for everybody" proposition from Aug. 1935 to May 1936, and producing no results, Aberhart began to plead for more time. He said: "Development of Social Credit from theory to actual working operation must be a process of deliberate planning in stages." Accordingly, in July 1936 he tried "prosperity bonds," or script to which stamps were to be attached, redeemable in two years. The venture fizzled out. Then came "registration" for the basic dividend; but the \$25 remained mythical. By Dec. 1939 the 1937 acts "to provide for the regulation of credit in the province of Alberta," and to tax the banks to raise funds for the basic dividend, had been declared ultra vires by the supreme court of Canada. The 1938 act concerning the taxation of securities, among others, suffered the same fate. And the judgments of the supreme court had been upheld by the privy council in London. By March 1942, nine of Aberhart's laws, mostly aimed at achieving social credit, had been disallowed.

An effort to establish a provincial bank in order to have closer control over currency also came to nothing. Greatest stir was made when the Aberhart government defaulted in 1941 on half of the interest payments on the provincial debt, but by doing so annual surpluses were achieved

When World War II broke out, the social crediters were already active in a program of post-depression reconstruction. Through the treasury branch and the Alberta Marketing board, a consumer bonus system was set up which (1) increased the purchasing power of consumers and (2) intensified home-market demand for Alberta products. Wartime requirements modified the need for this system, though it was continued throughout the period on a reduced scale. As the war progressed the government organized the Alberta Post-War Reconstruction committee, which presented its final report to the 1945 session of the assembly, and out of which came a new department of economic affairs, charged "to further and encourage orderly economic, cultural and social development for the betterment of the people of the province."

Included were plans for such postwar projects as an eight-year road-building program calling for expenditure of \$8,000,000 per year, a ten-year construction program to provide adequate provincial buildings totalling \$17,500,-000, nine large forestry projects, and a huge improvement scheme for 100,000 farm homes. The Alberta Power commission, founded in 1944, was instructed to expand rural electrification.

In 1946 the legislature passed the Alberta Bill of Rights, for the "establishing of every man in his own right and making him secure in that position by assuring him as a right of citizenship an opportunity to obtain a fair share of the abundant production which our vast resources make possible." It guaranteed minimum annual income of \$600 to every resident over 19 years, and free medical and educational benefits to all under

During the decade of lively political activity by the social crediters, the province did not suffer economically. Capital outlay in agriculture was enlarged, and income from sale of farm products increased. The ratio of mixed farming to grain farming improved, and in 1943 Alberta was the largest hogproducing province of Canada. Under the impetus of World War II, there was also noted industrial expansion: within the decade the number of industries increased by a third,

the number of employees by nearly two-thirds, and the value of finished products almost quadrupled. It was a record beaten only by Ontario.

With 80% of Canada's oil reserves in Alberta, and with wartime needs very large, it was perhaps natural that petroleum production expanded notably during the decade.

Many new wells were drilled. No serious effort was made, however, to tap the fabulously rich oil sands in the northern part of the province.

The most striking transportation expansion was in airways. In 1926, Edmonton had been granted the first airport licence issued to any city by the Canadian government, and this port was extremely active from 1926–46 in opening up the Northwest Territories by air. It was vital as the pivot of the Northwest Staging route during World War II.

During the decade Alberta became a model of fine arts instruction, with the founding and successful operation of the only Canadian annual summer School of Fine Arts at Banff, which attracted students from all parts of Canada and from many United States centres. (C. Cy.)

Alcohol, Industrial

Before 1937, the U.S. requirements for industrial alcohol fluctuated from about 40,000,000 gal. to 100,000,000 gal. annually. The production was chiefly from grains and molasses, and synthetic plants had limited capacity. By

1941 the need for more alcohol increased and new plans were made to expand the industry. Alcohol for beverages was restricted to increase the supply for war uses, including the manufacture of powder and synthetic rubber. Requirements were estimated in 1942 at more than 350,000,000 gal., three times prewar production. By 1943 production had passed this goal and rose to more than 500,000,000 gal. in 1944. Production was increased by building grain alcohol plants in the grain belt, by expanding plants using molasses from sugar cane in Cuba, and by building new plants to make alcohol from the waste products of wood pulp used in paper manufacture. The latter method had been developed in Sweden and proved successful.

The use of grains, particularly wheat, was increased from about 2,000,000 bu. in 1942 to more than 144,000,000 bu. in 1944. Since stocks of wheat were very large, the use of wheat was limited only by the alcohol-making facilities. By taking over the liquor-making plants the use of grains was increased. The amount of grain used declined somewhat early in the year 1945 because of the poor outlook for the new crop. In July the U.S. secretary of agriculture announced that no corn could be used for either industrial or beverage alcohol. In 1945 the rubber industry turned to using petroleum products and the requirements for grain alcohol became less urgent. The need for munitions declined while the need for grains for food and feed increased. Only 85,000,000 bu. of wheat were used for alcohol making in 1945 and practically none in 1946.

All of the blackstrap molasses from the 1944-45 Cuban sugar cane crop was purchased by the U.S. Defense Supplies corporation. Sugar was so scarce that allotments to

industrial users were limited to 70% to 80% of the amount consumed in the same months of 1941. In July 1945, this allotment was reduced to 50% as the food requirements became more urgent. The Defense Supplies corporation bought alcohol produced in Cuba and Puerto Rico from the 1943 and 1944 sugar cane crops. Wheat became so short in supply in 1946 that the use of wheat in distilling was prohibited.

U.S. Production of Industrial Alcohol, 1937-46 (In gallons)

1937 115,291,000 1942 266,572,000 1938 103,525,000 1943 385,447,000 1939 103,750,000 1944 519,977,000 1940 126,097,000 1945 176,240,000 1941 155,933,000 1946 21,216,000

The improved methods of making alcohol from various by-products, wood pulp, potatoes, low-grade grains, etc., were greatly improved and promised to provide a low-cost alcohol for use in the making of synthetic rubber and other new products. Grain alcohol was expected to continue to be expensive so long as the need for grain for food and stock feeds continued high. With the restoration of sugar production in the world the supply of molasses would be sufficient to provide a normal output from that source.

Alemán, Miguel

Alemán (1903–), Mexican statesman, was born in the small village of Acayucan, Veracruz state. His father, originally a village shopkeeper, became a revolutionary general who participated in the revolt that led to Porfirio Díaz's overthrow in 1911. The son graduated with honours in 1928 from the law school of the National university of Mexico and was admitted to the bar in Mexico City the same year. He acted as attorney for labour unions, held a number of minor political posts and was justice in a federal appeals court until his election to the senate. In 1936, when the governor-elect of Veracruz state was assassinated, Alemán resigned from the senate to assume the governorship. During his tenure, he carried on a vigorous campaign against illiteracy, devoting 47% of his budget to education.

In 1940, Alemán left the governorship to become presidential campaign manager for Gen. Manuel Avila Camacho. After his election, Avila Camacho appointed Alemán to the post of minister of interior and minister of government. Shortly after the Japanese attack on Pearl Harbor in Dec. 1941, Alemán took drastic measures to suppress axis espionage activities in Mexico. In June 1945, Alemán began his campaign for the presidency. His chief opponent was Ezequiel Padilla, a cabinet colleague who was foreign minister in the Avila Camacho government. Official returns of the elections, held July 7, 1946, gave Alemán 1,800,829 votes to 431,847 for Padilla. Inaugurated as president Dec. 1, 1946, Alemán announced his program would include greater extension of credit for both agriculture and industry and greater development of transportation. While promising Mexican workers protection of the state, he warned that his government would "maintain the interests of the country above those of individuals or groups."

Alexander, Albert Victor

), British statesman and politi-Alexander (1885cian, was born May 1, 1885 in Weston-super-Mare, England. He left school at the age of 13 to take a position as a junior clerk in the Bristol Education committee, meanwhile attending evening classes at a technical school. At the age of 18, he left his post to work for the Somerset County Education committee, staying with that organization for 17 years. During World War I, he joined the army as a private, rising to the rank of captain. After the war, Alexander, who had been long interested in the co-operative movement, was made parliamentary secretary of the Co-operative congress in 1920. In 1922, he was elected to parliament as a Co-operative party candidate serving until 1931. He was first lord of the admiralty in the MacDonald government, 1929-31. In the latter year he lost his seat in the Labourite defeat, and resumed his association with the Co-operatives. He was re-elected to parliament in 1935, and in 1940 Churchill renamed Alexander first lord of the admiralty.

After Churchill's dissolution of the coalition government in May 1945, Alexander resigned from the cabinet. In his campaigning on the Labourite ticket in the general elections, he assailed Churchill as a "stooge" for reactionary interests. On Aug. 3, 1945, Prime Minister Attlee renamed Alexander to head the admiralty.

In the summer of 1946, Alexander temporarily replaced Foreign Minister Bevin, who was in ill health, at the 21-nation peace conference in Paris. He repudiated soviet charges that the U.S. and Britain were attempting to use undue influence on former axis states.

In the sweeping plans for reorganization of Britain's army, navy and air force, Prime Minister Attlee created a new ministry, Oct. 4, 1946—the ministry of defense—and appointed Alexander at its head with control of the three armed services.

Alexander, Viscount

Viscount Alexander of Tunis (Harold Rupert Leofric George Alexander) (1891-), British army officer and statesman, was born Dec. 10, 1891, in County Tyrone, Ireland. The 3rd son of the 4th earl of Caledon, he was educated at Harrow and at the Royal Military college, Sandhurst. He entered the regular army in 1911 as a second lieutenant. Among the first contingent of the "Old Contemptibles" to be shipped to France during World War I, Alexander commanded a regimental battalion, was twice wounded in action and won the D.S.O., the M.C. and the Legion of Honour. After serving in a number of high military posts in Britain and India, he returned to England in 1938 and again went overseas to France as commander of the British 1st division, at the outbreak of World War II. Later, he helped to organize the successful British evacuation (May-June 1940) from the Dunkirk beaches. In Feb. 1942, he was made commander of the British army in Burma. Again forced on the defensive, he beat a hasty retreat to India. The following summer he was transferred to Egypt, where he was appointed commander in chief of British Imperial forces in the middle east (Aug. 18, 1942). Under his over-all direction, the British 8th army chased Marshal Rommel's Afrika Korps out of Egypt and Libya. In Feb. 1943, Alexander was appointed Gen. Eisenhower's deputy and field commander of all Al-

lied armies in North Africa. He helped to plan the strategy for the Sicilian and Italian invasions in 1943. Gen. Alexander was promoted to the rank of field marshal June 4, 1944, and on Nov. 26, his appointment as supreme commander of the Mediterranean theatre was announced. In Feb. 1945, Marshal Alexander attended the Yalta conference and in May 1945, he accepted the surrender of German troops in northern Italy. During the controversy that arose over Trieste, Alexander challenged the authority of unilateral Yugoslav occupation of the city and nearby disputed areas. On July 31, 1945, he was appointed by King George VI as governor-general of Canada, succeeding the Earl of Athlone. Alexander, who had been made a baronet in 1942, was elevated to the peerage, Jan. 1, 1946, as Viscount Alexander of Tunis. He assumed his post as governor-general of Canada, April 12, 1946.

Alexei

Patriarch Alexei (Sergei Vladimirovich Simansky) (1877—), Russian ecclesiast and patriarch of the Russian Orthodox Church, was born Oct. 27, 1877, in Moscow. A graduate of the Moscow University law school, 1899, he attended the Moscow Ecclesiastical seminary and was graduated from the latter school in 1904 with a degree of doctor of theology. While still at the seminary, he was made a deacon (1902), assumed the name Alexei and became a priest the following year. Alexei, who was ordained a bishop in 1913, served as archbishop of Novgorod, 1932–33, and metropolitan of Leningrad, 1933–43. He was made metropolitan of Leningrad and Novgorod in 1943.

After the German invasion in 1941, Stalin, in his efforts to rally all soviet citizens to the defense of the fatherland, relaxed his opposition to the church and put a quietus on the activities of atheist organizations, particularly the "Godless League." These moves facilitated resumption of religious activities in Russia and Sergei, Alexei's predecessor as patriarch, urged the faithful to join wholeheartedly in the country's efforts to repel the invaders. This policy was continued by Alexei, who remained in Leningrad during the siege to organize the church in support of the red army. He was decorated for these services by the soviet government. In 1943, Alexei was made a permanent member of the Holy Synod.

After the death of Sergei in 1944, Alexei was named acting patriarch of the Russian Orthodox Church. On this occasion, he warmly renewed the church's pledge of loyalty and in a letter to Stalin, he wrote: "Most revered and dear Joseph Vissarionovich, I ask you to accept these assurances and believe in the feeling of profound love and gratitude to you with which all the church workers, guided by me, are now inspired."

Alexei was unanimously elected patriarch by the council of bishops that convened in the Sokolniki cathedral in Moscow Feb. 2, 1945. Some three months later (May 12), he was quoted in the newspaper *Izvestia* as saying that the Orthodox Church's principal achievement of the war was to "display to the world its complete unity with the government."

Alfalfa

The alfalfa crop grew steadily in favour among U.S. farmers during the decade 1937–46. In the ten-year period prior to 1937, an average of about 12,000,000 ac. was grown, and production averaged nearly 25,000,000 tons of hay. Acreage began to increase in 1940, when it reached

13,903,000 ac. and produced a crop of 30,578,000 tons. Increases occurred again in 1941 and also in 1942 when 15,814,000 ac. returned a record crop of 36,478,000 tons. There was a slight decline in acreage in 1944 and 1945, but the crop continued above average because of good yields.

The production of alfalfa seed began to increase in 1939, when more than 1,013,000 ac. were harvested and a record crop of 1,515,000 bu. obtained. The acreage declined in the period 1940–42 and rose again somewhat in 1944 but not to the record of 1939. The farm price of seed was only \$8.76 per bu. in 1940, but rose to \$20.22 in 1944 and to \$21.00 in 1946. The leading states in alfalfa seed production were Kansas, Oklahoma and Nebraska, with Arizona, Idaho, Montana, Minnesota and Utah next in order on the average.

Prices for alfalfa hay increased after 1928, when the farm price averaged only \$7.86 per ton. The rise was steady until early in 1946 it averaged \$18.00 per ton. No. 1 baled alfalfa at Kansas City rose from \$14.00 per ton in 1938 to more than \$30.00 per ton in 1946. Prices varied widely between regions, being \$9.72 per ton in the west north central region in April 1946, compared with \$22.50 in the south Atlantic states and \$19.90 on the Pacific coast. The declining numbers of dairy and beef animals began to show in the reduced market demand, offset to some extent by the shortage of feed grains. The production of all hay for the country as a whole was high relative to the number of livestock to be fed. The need for more hay of high-feeding quality was felt particularly in the southeastern states, and the U.S. department of agriculture urged an increase in this region in 1946 while suggesting a total hay acreage only 5% above the 1937-41 average. It was estimated that hay and pasture accounted for more than 50% of the feed of livestock. Alfalfa had come to be considered the most important not only because of its high feed value but also because of the beneficial effect on the

The harvesting of hay was handicapped by the scarcity of iron wire bale ties in 1945 and 1946. Limitations of the raw metal to manufacturers so restricted the output of the ties that many farmers could not use their hay balers. The use of modern machinery rapidly changed the methods of handling hay at harvest, and a large part of the crop now was baled in the field as it was cut. New hay-drying ventilating systems were installed in barns to hasten the curing

*Preliminary estimate (subject to revision in 1947).

of the hay and improve its feeding quality.

This is particularly important with alfalfa, to conserve the leaves.

Aliens

In the United States, the permanent quota limit law of 1924 remained in effect throughout the decade 1937-46; it allotted an annual quota to various designated nationalities, more than 95% European. The act administered by the commissioner of the immigration and naturalization service of the U.S. department of justice, specified three general classes of aliens for admission to the United States: (1) quota immigrants; (2) immigrants not subject to numerical (i.e., quota) limitation; and (3) nonimmigrants admitted for temporary stay. The quota provisions were based upon "national origins" as defined in the law. National origins were determined on the basis of the nationality composition of the total white population as enumerated by the census of 1920. To determine the origins of the various groups in the population, examination was made primarily of statistics of immigration and emigration and of census reports. The accompanying table

Annual Quotas, and Quota Aliens Admitted, 1939 and 1945, by Countries or Regions of Birth and by Sex.

*Includes aliens to whom visas were issued during the latter part of the preceding

rections allens to whom visas were issued auring the latter part of the preceding year which were charged to the quota for that year.

†Quota for colonies, dependencies, or protectorates included with allotment for the European country to which they belong. The annual quota for 1939 was 153,774. Addition of 105 on Feb. 8, 1944, accounts for the annual quota total of 153,879 listed above. On July 4, 1946, an additional 50 was allotted to the quota for the Philippine Islands. With this latter revision the total for all countries becomes 153,929.

lists the annual quotas under the Immigration act of 1924, and the number of quota aliens admitted to the United States during the two fiscal years 1939 and 1945.

Registration.—The registration of aliens in 1940 provided the United States government with a detailed inventory of its alien population. With the exception of government officials and members of their families, all aliens 14 years of age and over who were in the United States on Aug. 27, 1940, and remained in the country for 30 days or longer were required to be registered and fingerprinted by Dec. 26, 1940. After that time aliens entering the United States for 30 days or more were registered and fingerprinted before admission. Aliens entering for less than 30 days were not required to be registered and fingerprinted, but if after arrival they remained more than 29 days such action had to be taken. Generally, registration and fingerprinting in the United States or at ports of entry were conducted by designated employees of the immigration and naturalization service. United States consular officers were authorized to register and fingerprint aliens abroad who applied for visas.

Registered resident aliens were required to notify the service in writing of each change of address within five days of the date of change. Aliens who entered the United States temporarily as students, visitors or otherwise than for permanent residence were required to give notice in writing of their address in the United States at the expiration of each three months' period.

As of Dec. 26, 1940, there were 5,009,857 registered aliens in the United States, Alaska, Hawaii, Puerto Rico and the Virgin Islands of the United States. This figure was the result of the registration which began Aug. 27, 1940, and continued through Dec. 26 of that year. An estimate based upon the alien registration records for the initial registration period indicated that on June 30, 1945, there were 3,050,000 resident aliens. Net migration, naturalization and mortality factors were used in making the estimate.

As of June 30, 1945, it was estimated that the median age of the alien population was 53 years. This was an estimated increase of 5 years over the median of 48 years indicated by the 1940 registration. During the same period, according to the U.S. census bureau, the estimated median age of the total population increased from 29 years in 1940 to 29.7 in 1945. The disproportion of certain age groups among the alien population, when compared with the general population, was illustrated particularly in the very young and the older age groups. Persons under 20 constituted 34% of the total population, but only 3% of the alien population. At the other extreme, those 45 years of age and over made up 27% of the general population, but 58.5% of the alien population.

Almost 75% of the registered aliens were born in Europe. Twenty per cent came from neighbouring countries in North and Central America, and the remainder from South America, Africa, Asia and the islands of the Pacific. Listed below are the main countries in order of rank for registered aliens according to country of birth, as of Dec. 26, 1940 (figures to nearest thousand):

Italy, including Sicily and Sardinia.703Canada.467Poland.446Mexico.424Purplic including Pusis in Asia.
Russia, including Russia in Asia370
Germany321
Great Britain, including England, Scotland
and Wales300
Austria194
Eire 160
Hungary118
Sweden
Japan 93
Lithuania
Philippine Islands
Greece 83

In 1940 some 80% of the registered aliens were living in the following ten states (figures to nearest thousand): New York, 1,258; California, 542; Pennsylvania, 370;

Japanese truck gardeners weeding onions at a relocation centre in California during 1943

Massachusetts, 364; Illinois, 325; Michigan, 303; New Jersey, 279; Texas, 214; Ohio, 203; Connecticut, 158. The registration data revealed a high concentration of aliens in urban centres.

One-third of the total was located in the five largest cities—New York, Chicago, Philadelphia, Los Angeles and Detroit. Almost 70% were concentrated in urban centres of more than 50,000 population.

Of the approximately 5,000,000 registered aliens, 13% arrived during the 1930s and 27% during the previous ten years. More than 70% of the total had arrived in the United States before 1924. The estimated median duration of residence in the country was 25 years. An estimated 734,000 were illiterate, two-thirds of whom were women.

The percentage of illiteracy rose sharply among those 45 years of age and older. The total noncitizen population of the country consisted of 2,341,000 males and 2,669,000 females. Hence, there were 88 males for every 100 females.

Naturalization.—For the nine fiscal years 1937 through 1945, a yearly average of 147,000 declarations of intention—first citizenship papers—were filed. The four prewar years through 1940 accounted for a 172,000 yearly average, and the average for the five war years 1941 to 1945 was 127,000 per year. This decrease occurred principally in

the years 1944 and 1945, when the figures were the lowest since statistical records of naturalization were begun by the federal government in 1907.

Petitions for naturalization averaged 261,000 per year for the nine-year period, 208,000 yearly for the four prewar years, and 304,000 for 1941 to 1945. Petitions filed totalled approximately 900,000 for the years 1943, 1944 and 1945.

Except for slight decreases in 1938 and 1943, the number of persons naturalized each year increased considerably between 1937 and 1944. The figure of 442,000 for 1944 was the highest recorded, but the following year there was a decrease to 231,000. For the nine years 1937 through 1945, the yearly average of persons naturalized was 255,000. Of the 992,000 naturalizations covering the years 1943–45, 109,000 were granted to members of the U.S. armed forces.

Provisions in the Second War Powers act, approved March 27, 1942, made available an expeditious naturalization procedure to noncitizen members of the United States armed forces during World War II. The statute provided a judicial naturalization process for those residing within the jurisdiction of a naturalization court, and an administrative process for those serving outside the country. Although most of the naturalizations took place in the state and territorial courts of the United States, approximately 14,000 occurred outside the United States. Citizenship was conferred on this latter group by designated representatives of the immigration and naturalization service under procedure which for the first time authorized the granting of naturalization under the administrative process. The naturalizations indicated took place between Dec. 1, 1942, and June 30, 1945, in the following areas (figures to nearest thousand):

Great Britain and Northern Ireland	o
North Africa	2
New Guinea .	2
Other Pacific	2
Italy	1
France	1
Asia	1
Australia and New Zealand	7

Other areas where this type of naturalization occurred were: Panama Canal Zone, Iceland, Canada, Caribbean area, South America, Greenland, Belgium, Newfoundland, other Africa and Bermuda.

Aliens of enemy nationality could be naturalized under prescribed safeguards. The case of each alien enemy applicant for naturalization was thoroughly investigated by the immigration and naturalization service, and favourable recommendations were made only where loyalty was established without question. Naturalizations for alien enemies, compared with the total naturalizations of aliens from all countries, follow:

Alien enemy	941	1942	1943	1944	1945
naturalizations 8: Percent of total			61,919	191,273	97,322
naturalizations Total naturalizations27	29.4 7,294	13.7 270,364	19.4 318,933	43·3 441.070	42 1 231,402

There were approximately 2,300,000 naturalizations for the years 1937 to 1945. The principal nations to which most of these new citizens formerly owed allegiance (figures in thousands) were: British empire, 583; Italy, 363; Poland, 260; Germany (including Austria), 256; U.S.S.R., 159; Czechoslovakia, 83; Sweden, 58; Yugoslavia, 57; and Hungary, 54.

Alien Enemies.—Under the Nationality act of 1940, alien enemies included natives, citizens, denizens, and

subjects of the countries against whom the United States had declared war. These countries were Japan, Germany. Italy, Hungary, Rumania and Bulgaria. Aliens of enemy nationalities at the outset of the war numbered almost 1,275,000 or one-quarter of the entire alien population. Those of Italian nationality numbered 703,000; Germans, 321,000; Hungarians, 118,000; Japanese, 93,000; Rumanians, 33,000; and Bulgarians, 5,000. By authority of presidential proclamations of Dec. 7 and 8, 1941, and Jan. 14, 1942, a series of regulations was promulgated by the department of justice affecting the conduct of citizens or subjects of Japan, Germany and Italy, 14 years of age and older. During Oct. 1942, aliens of Italian nationality, except those already interned or under parole, were excepted from the regulations for alien enemies by order of the attorney general.

The regulations which affected aliens of German and Japanese nationalities placed restrictions on their travel and prohibited them from owning certain articles, such as cameras, short-wave receiving and transmitting sets and firearms. They were not permitted to make any air flights, or to change their places of residence or employment without notifying the authorities. The regulations re-

sion. Such aliens were interrogated by Alien Enemy Hearing boards to determine whether they should be interned for the duration of the war, paroled, or released unconditionally. The regulations of Dec. 7 and 8, 1941, relating to the possession of certain prohibited articles and to travel within the borders of the United States, were revoked by the president on Dec. 12, 1945.

Dangerous alien enemies ordered interned by the attorney general were kept in internment camps operated by the immigration and naturalization service. From the beginning of U.S. participation in the war until Aug. 1945, 24,886 aliens of enemy nationality were included under alien enemy proceedings. Early in 1941, the wartime internment program was begun with the detention of crew members of the scuttled German steamship "Columbus" and of Italian seamen apprehended for, or to prevent,

sabotage to their ships in U.S. ports. As a result, three internment camps were in operation when the United States entered World War II. When the principal breadwinner was interned, his family frequently requested to be interned with him. This was allowed if careful investigation indicated that internment was in the best interest of the family. One of the camps, at Crystal City, Tex., was used for the detention of internees and their families. In May 1945, it included 3,326 persons, almost half of them children. All civilian alien enemy internees originally in the custody of the army were transferred to the jurisdiction of the immigration and naturalization service by June 1943. A total of 4,120 internees were affected by the transfer. Of the 9,220 alien enemies detained at the end of the fiscal year 1943, 5,988 came from continental United States and Puerto Rico, 2,349 from Latin America, and 883 from Alaska, Hawaii and other Pacific islands.

During the fiscal year 1945, the population of alien enemy detention camps increased from the 1944 figure of 6,238 to 7,364. In the same period, 1,658 were released from the camps, compared with 5,528 released during the previous year. Of this number, 792 were repatriated, 627 paroled, 119 discharged, 88 interned at large and 32 died. During 1945, of persons interned, 5,211 were Japanese, 2,107 German, 25 Italian, and 21 of the other enemy nationalities. Of the total, 1,120 were persons who applied for internment to join husbands or fathers in one of the family internment camps; 3,015 were persons apprehended under presidential warrants; 1,956 were persons brought to continental United States from Alaska and Hawaii; and 532 were seamen who had been members of crews of enemy merchant vessels taken into custody in ports of the United States.

U.S. Legislation.—The act of May 14, 1937, placed restrictions on nonquota and preference-quota immigrants. Certain immigrants were excepted from exclusion from the United States, and deportation was directed for aliens who had obtained visas through fraudulent marriage.

The act of June 25, 1936, relaxed the requirements for naturalization as to continuous residence for aliens absent from the country during employment by the United States government, an American institution of research, or an American concern engaged in promotion of foreign trade and commerce of the United States. The procedural requirements for obtaining this exemption were made more stringent by the act of June 29, 1938. The act of Aug. 9, 1939, extended similar benefits to aliens absent in the capacity of clergymen.

The act of July 27, 1939, provided for return of Filipinos to the Philippine Islands at United States expense (similar statute, July 10, 1935).

On June 28, 1940, the Alien Registration act of 1940 was passed. This act prohibited subversive activities such as urging disloyalty and advocating the overthrow or destruction of the government of the United States. It provided additional grounds for the exclusion and deportation of aliens. Permission was granted in certain deportation cases for aliens of good moral character to depart voluntarily in lieu of deportation, or to obtain suspension of deportation if such action would result in serious economic detriment to members of the families. Title III of the act provided for the registration and fingerprinting of aliens in the United States and of those seeking to enter.

The act of July 2, 1940, extended the privilege of repatriation to native-born American women who had lost United States citizenship by marriage to aliens prior to

Sept. 22, 1922, whose marital status had not terminated, but who had resided in the United States continuously after their marriage.

Another act of July 2, 1940, allowed naturalization, without a declaration of intention, of an alien who had entered the United States before his 16th birthday and who had filed his petition for naturalization before his 22nd birthday.

The act of Aug. 16, 1940, provided exemptions from the normal residence and certificate of arrival requirements to soldiers serving in the regular United States army.

The Nationality act of 1940 (Oct. 14, 1940) was a codification and revision of existing laws. It provided that certain persons who lost their citizenship by entering or serving in the armed forces of a foreign state were entitled to enter the United States as nonquota immigrants for the purpose of recovering their citizenship; and specified that a former citizen of the United States, expatriated solely through the expatriation of a parent, need not comply with the requirements of the immigration laws if he returned to the United States before the age of 25 years.

The nationality provisions included the following major innovations: (1) provision for appointment by the commissioner of designated naturalization examiners to hear testimony for the courts and extension of the system to state courts; (2) liberal exemption from some naturalization requirements for persons serving in the armed forces and on vessels; (3) reduction of the required waiting period after filing the petition for naturalization from 90 days to 30 days, and increase from 30 days to 60 days of the period immediately preceding general elections when naturalization was prohibited; (4) authorization for naturalization of natural children and adopted children on petition of the citizen parent or parents; (5) expansion of the categories of persons eligible for naturalization by permitting naturalization of descendants of races indigenous to the western hemisphere; and (6) authorization by the commissioner of immigration and naturalization to prescribe the nature and scope of examinations of petitioners for naturalization with respect to their understanding of and attachment to the fundamental principles of the constitution.

The act of June 21, 1941 (amending the act of May 22, 1918), related to the prevention of departure from and entry into the United States in time of war.

Title X of the Second War Powers act of March 27, 1942, provided a simplified procedure for the naturalization of noncitizens serving in the armed forces during World War II, including provisions for administrative naturalization for those stationed outside the United States.

The act of April 2, 1942, extended to former citizens who had lost citizenship by reason of service in the armed forces of one of the Allies during World War II, an expeditious method of naturalization. Persons in this category could become naturalized by taking the prescribed oaths before any diplomatic or consular officer of the United States abroad.

The acts of April 29, 1943, Dec. 23, 1943, Feb. 14, 1944, June 28, 1944, Dec. 22, 1944 and July 3, 1945, authorized the importation of agricultural and other labourers from the western hemisphere for employment for a limited wartime period. The acts further provided for the transportation, maintenance and other expenses in connection with their importation. Provisions of the immigration laws relating to aliens generally were waived in behalf of such labourers.

The act of July 13, 1943, amended the Immigration act

of Feb. 5, 1917, in order to relax, during the time the United States was at war, normal requirements as to places to which an alien could be deported. It provided that under certain conditions an alien was deportable to the country where his recognized government-in-exile was located, or to a country proximate to the one of which the alien was a citizen or subject, or, with the consent of the country of which the alien was a citizen or subject, to any other country.

An important measure was the repeal on Dec. 17, 1943 of the Chinese Exclusion laws. This legislation originated in 1882 and had been retained on the statute books for 61 years, during which time it was subjected to many amendments and revisions. The congressional action in 1943 permitted a small number of the Chinese people to enter the United States for immigration purposes. The new legislation also removed the previously established prohibitions against naturalization of persons of the Chinese race as U.S. citizens, and established a yearly immigration quota for Chinese persons of 105.

The act of Jan. 20, 1944, amended the Nationality act of 1940 to provide that United States citizenship lost through desertion from the armed forces could be regained by restoration to active duty with such forces in time of war. This act further amended that statute so as to make certificates of citizenship available to persons who acquired that status at birth outside the United States, its territories, and possessions, or at birth on or after Jan. 13. 1941, in an outlying possession of the United States.

On July 1, 1944, congress consolidated and revised the laws relating to the public health service, which included the care and treatment of seamen, examination of aliens, quarantine and the use of immigration station hospitals. The act also provided for hospital treatment of alien convicts who were narcotic addicts and for release therefrom to this service of those entitled to discharge and subject to deportation.

The act of Sept. 27, 1944, further amended the Immigration act of Feb. 5, 1917, by adding to the classes of excludable aliens, persons who had departed from the jurisdiction of the United States to evade training or service in the armed forces during time of war or during a time declared to be a period of national emergency. It also provided for loss of nationality by any national of the United States who departed or remained outside the jurisdiction for such purpose.

The act of Sept. 28, 1944, increased the fees for filing declarations of intention and petitions for naturalization and eliminated the fee for a certificate of arrival.

The act of Dec. 19, 1944, eliminated in certain cases the liability of transportation companies to fines and penalties for bringing aliens to the United States without proper documents.

The act of April 30, 1945, provided for the imposition of severe penalties on any person guilty of procuring or attempting to procure the escape of any prisoner of war or interned alien enemy held by the United States or any of its allies.

The act of Oct. 29, 1945, amended the Immigration act of 1924 by adding to the classes excluded on the ground of ineligibility to citizenship, certain aliens of neutral countries who applied for relief from training and service in the armed forces of the United States.

The act of Dec. 28, 1945, expedited the admission to the United States of alien spouses and children of citizen members and former members of the armed forces by exempting them (for a period of three years) from the usual documentary requirements and from exclusion on

the ground of certain physical and mental defects as listed in the act of Feb. 5, 1917.

The act of Dec. 29, 1945 (International Organizations Immunities act), added to the classes of nonimmigrants, foreign government representatives to certain international organizations, the personnel of such organizations and their immediate families. In addition, the statute granted to such persons the same privileges in connection with entry into and departure from the United States as those accorded to officers and employees of foreign governments. (U. C.)

Great Britain.—The control of aliens in Great Britain continued to rest on the Aliens Restriction act, 1914, and the Aliens Restriction (Amendment) act, 1919; but the effective instrument was an order in council, the Aliens order, 1920. All aliens, with certain limited exceptions, e.g., diplomats and members of Allied forces, were registered with the police and were issued a certificate containing a photograph and particulars of residence, occupation and nationality.

	Registration of Aliens in	Great Britain	
	1933	1937 1939	1946
Austrian	4,344	11,849 11,989	16.485
Belgian	4,940	4,685 4,207	11,438
Czechoslovak	1,274	2,123 7,930	10,171
Dutch	5.086	5,607 5,668	16,286
French	12.785	13,195 11,613	13,582
German		20,986 62,244	37,824
Italian		20,950 19,127	16.755
Polish		6,181 8,776	20,226
U.S.A	13.579	14,421 13,665	12,605
Others	92,385	93,656 92,855	109,404
Total:	174,243	193,653 238,074	264,776

The German (nazi) government created 500,000 potential Jewish refugees and the occupation of Austria a further 200,000. Great Britain was not an immigrant country, but temporary refuge was given to those in immediate danger. In Sept. 1939, the 122 tribunals set up to examine enemy aliens dealt with 71,553 persons and classified 55,600 as "refugees from nazi oppression." Czechs were treated as friendly aliens. A special Czech tribunal dealt with 10,469 Czechs, recommending internment in one case only, and the imposition of special restrictions in another.

There was no general internment of enemy aliens until May 1940. Between May 12 and July 24, internment of Germans and Austrians was carried out in three stages, beginning with those in the coastal belt and those subject to special restrictions. The total number of persons interned, including Italians, Japanese and nationals of other axis satellites, was 27,568. The policy was a temporary one to meet a threatened invasion, and on Aug. 1, 1940, a White Paper was issued specifying categories of eligibility for release. The grounds fell broadly into three classes: age, ill-health and usefulness for national service. The effect was to place on the internee the onus of justifying his claims to liberty. The following table shows the position in May 1946:

·										Germans and Austrians	Italians	Others	Totals
Still interned										21	4		25
Died in internment			٠		٠					242	473	4	719
Repatriated		٠								1,194	200	148	1.542
Released	•	•	٠	•	•	٠	•	•	٠	20,510	4,155	617	25,282
										21.967	4.832	769	27.568

Between 1937 and 1946, 2,585 deportation orders were made, an average (excluding 1940 when the number was 1,099) of 165 orders per annum. Persons actually deported numbered 1,054; 1,450 persons against whom deportation orders were made were detained, on grounds of public security or order, when deportation was impracticable.

This wartime provision of the Aliens order was withdrawn in Dec. 1045.

The Allied governments in exile and their officials were granted diplomatic status by the Diplomatic Privileges (Extension) act, 1941. The Allied Forces act, 1940, authorized the exercise of powers of discipline and internal administration by the Allied commands, and the Allied Powers (War Service) act, 1941, the conscription of Allied nationals. The Alfied Powers (Maritime Courts) act, 1941, set up maritime courts for the discipline of merchant seamen. The United States (Visiting Forces) act, 1942, took U.S. forces outside the jurisdiction of British courts.

Between 1937 and Nov. 1940, when naturalization was suspended, 8,046 certificates were granted. British-born women married to enemy aliens and widows and persons whose naturalization was required in the national interest were exceptions to the suspension policy, and 4,421 certificates were issued under one or other of these exceptions. After naturalization of other applicants was resumed in Nov. 1945, 2,151 certificates had been issued up to mid-Oct. 1946. Under the British Nationality and Status of Aliens act, 1943, Frenchmen serving in the British forces were eligible for naturalization under special arrangements. (See also Census Data, U.S.; Immigration and Emigration; War and Defense Agencies.) (W. B. L.)

Alimentary System, Disorders of

Adequate treatment of oesophageal lesions continued to be a challenge to the medical profession during the decade 1937-46. Difficulties in the diagnosis of oesophageal lesions were emphasized by M. Loeper, Mlle. Riom and P. Perreau, who pointed out that such widely divergent symptoms as paralysis of a vocal cord and cardiovascular disturbances may be secondary to lesions of the oesophagus. If the intercostal nerves and the sympathetic nervous system are involved, vascular and ocular disturbances, severe pain and anomalies of the production of sweat will be present. The most common symptom in oesophageal lesions is trouble with swallowing. Pain, however, may be one of the earliest manifestations of oesophageal disease, and if it is not then accompanied by difficulty in swallowing, it may prove to be misleading. An obstacle to the clear understanding of the importance of oesophageal pain continued to be the lack of knowledge concerning the nerves that control the oesophagus. The upper portion of the oesophagus is supplied by the recurrent laryngeal nerves and the lower portion by the oesophageal plexus formed by the intermingling of the right and left vagus nerves. H. J. Moersch and J. R. Miller pointed out that the vagus nerve has communications with the glossopharyngeal nerve, the spinal accessory nerve and the first and second cervical nerves, that the vagus fibres are next to the descending tract of the trigeminal nerve and that a somatic sensory branch of the ganglion nodosum of the vagus innervates the external auditory canal. Sympathetic nerve fibres having their origin from the inferior cervical ganglion and the first to ninth thoracic sympathetic ganglia also serve to convey painful stimuli from the oesophagus. Although the phrenic nerve does not directly supply the oesophagus, this nerve may, because of the close relationship between the oesophagus and diaphragm, serve to transmit painful stimuli. Knowledge of these facts made the many areas in which pain is felt related to the oesophagus understandable. In general, oesophageal pain depends on the state of tension of the oesophagus. The character of such pain varies widely; the more severe it becomes, the wider is its distribution. Pain caused by disturbances in the upper portion of the oesophagus is more likely to be situated over the thorax at a point corresponding to the underlying oesophageal lesion. Disturbances in the lower portion of the oesophagus give rise to a much more diversified distribution of the pain.

F. C. Lendrum studied the oesophagus in cases of spasm at the lower end and found a striking loss or complete absence of ganglion cells from the myenteric plexus of nerves. After the destruction of this plexus, sympathetic fibres to the terminal portion of the oesophagus act without opposition; the terminal part of the oesophagus then does not relax normally with the swallowing reflex and inability to swallow results. To explain the varying anatomic pictures, Lendrum introduced the term "compensated" and "decompensated" cardiospasm (spasm of the lower end of the oesophagus). In the presence of early and moderate cardiospasm, the oesophagus dilates only slightly and compensates for the increased internal pressure by thickening of the walls; long-continued severe pressure, however, overcomes this resistance and the oesophagus dilates prodigiously and stretches lengthwise.

The treatment of varicose veins in the oesophagus made significant progress. D. M. Juzbašić proposed the interruption of all venous afferent tracts traversing the small omentum, interruption of similar tracts from the region of the spleen and the performance of a modification of the Talma operation to facilitate the discharge of the blood from the portal vein into the vena cava. H. J. Moersch reported the successful obliteration of oesophageal varices by the injection of a sclerosing substance guided by endoscopic visualization.

The successful treatment of carcinoma of the oesophagus continued to be a difficult problem to both the physician and the surgeon. The advent of chemotherapeutic drugs and antibiotic agents made it possible to remove lesions of the oesophagus surgically, with incomparably less immediate risk than was formerly the case. Insufficient time had elapsed by the end of the decade to permit a satisfactory estimate of the ultimate results which might be expected from this difficult and radical procedure.

Stomach and Duodenum.-Much study of the physiology of gastric secretion was undertaken. Franklin Hollander pointed out that the secretion of the stomach wall is an isotonic solution of practically pure hydrochloric acid. The normal variations in the acid and neutral chloride concentrations of the juice of the fundic pouches are caused by a buffer-containing secretion which neutralizes and dilutes the fluid. This buffer secretion plays a major role as an intragastric agent in the normal control of gastric acidity, a role that is more important than duodenal regurgitation as an extragastric agent. C. M. Wilhelmj, F. T. O'Brien and F. C. Hill demonstrated clearly that the pyloric segment exerts a specific stimulating influence on the acid-secreting mechanism of the body of the stomach, and is thus of importance in the intragastric chemical phase of the secretion of acid. Basal gastric secretion was studied by A. L. Bloomfield, C. K. Chen and L. R. French. They found that there was no correlation between the level of gastric acidity obtained by stimulation with histamine in control cases, as compared with cases of duodenal ulcer. On the basis of their observations, it appeared that a basal acidity of more than 100 is almost positive evidence of the presence of duodenal ulcer, and that a basal acidity of more than 120 makes the diagnosis definite. The authors recommended study of basal secretion as a simple and informative procedure in respect to gastric secretion. Irving Ehrenfeld and Mills Sturtevant found that the

smoking of tobacco caused a significant increase in gastric acidity, lending support to the clinical observation of the harmful effect of tabagism in the course of symptoms of dysphagia. K. Westphal and H. Weselmann confirmed the fact that tobacco has an injurious effect on the stomach. They attempted to measure the extent of injury caused by nicotine to the gastric mucous membrane by its effect on the gastric cell count and by gastroscopic and roentgenoscopic examinations in the human being. They substantiated their findings by animal experimentation. Persons who have a labile vegetative nervous system particularly should be warned against the hazard of excessive smoking.

The experimental production of ulcer by the oral administration of cinchophen, and the subcutaneous use of a histamine-beeswax mixture, gave the physiologist useful tools for the advancement of understanding of the genesis and treatment of benign duodenal and gastric ulcer.

J. A. Roth and A. C. Ivy found evidence that caffeine and coffee taken orally are powerful stimulants of both the acid and pepsin content of the gastric juice in man and the cat. The intravenous or intramuscular administration of caffeine likewise provokes a copious flow of gastric juice. This work implied that the excessive use of caffeine-containing beverages may play a contributory role in the pathogenesis of gastroduodenal ulcer in man. The same workers found that caffeine and histamine have a synergistic effect in relation to gastric secretion; a similar synergistic effect was noted with respect to alcohol and caffeine.

An interesting approach to the problem of duodenal and gastric ulcer was made by D. J. Sandweiss and A. C. Ivy and associates. A substance derived from the mucosa of the small bowel called "enterogastrone" and a substance extracted from the urine called "urogastrone" were demonstrated to exert an inhibiting effect on the gastric secretion of experimental animals. These observations opened new avenues in the treatment of gastroduodenal ulcer. Much work still remained to be done, however, before any valid prediction of the worth of these substances in the treatment of the patient with ulcers could be made.

There was much interest and real advance in the understanding of the relationship to dyspepsia of diffuse gastric mucosal changes. This was primarily because of the development, to a high degree of perfection, of the flexible gastroscope. Much of the value of the gastroscopic examination, however, still rested with the skill and experience of the examiner. In recognition of this, attempts were made to render gastroscopic interpretation less subjective and more objective. M. J. Heilpern, O. Porges and H. Hofmann developed a small photographic apparatus which could be introduced into the stomach and which permitted the making of a photograph of the interior of the stomach. Later, Norbert Henning and Heinz Keilhack developed an apparatus which operated on the principle of a mirror reflex camera, which permitted better control and allowed for the making of photographs of selected areas of the gastric mucosa. The method had definite practical limitations, but commended itself to further development because of the aid it offered in teaching and also because it was the only method which resulted in an objective record to which later reference for comparative purposes was possible. Another refinement of the gastroscopic procedure was that which permitted the taking of specimens for biopsy from the areas visualized by the flexible gastroscope. The taking of a specimen for biopsy from the gastric mucosa had long been possible through the direct-vision rigid instrument, but the value of this method was necessarily restricted because much of the interior of the average stomach cannot be seen through the rigid instrument. Bruce Kenamore developed a workable attachment to the Wolf-Schindler gastroscope which permitted the taking of specimens for biopsy from both benign and malignant lesions. Should this instrument prove to be practical and safe, it would seem to give real promise as an aid in the recognition of small neoplastic gastric lesions.

Probably the most important contribution to gastroenterologic practice rendered by the agency of the gastroscope during the decade was clarification of the understanding of gastritis. The fact that gastritis exists and that it is an important cause of dyspepsia was generally accepted. Rudolf Schindler pointed out that gastroscopic examination may be extremely helpful in proper evaluation of the nature of a circumscribed gastric ulcer. He believed that the observations made at gastroscopic examination might be superior to inspection of the gross specimen, and might be equalled only by microscopic examination as a method of distinction between a benign gastric ulcer and a neoplastic one. Although this observation was perhaps somewhat optimistic, yet the gastroscope in expert hands had proved to be a useful tool in the recognition of early carcinoma of the stomach.

A. H. Douthwaite and G. A. M. Lintott examined the stomach gastroscopically after the ingestion of acetylsalicylic acid and dilute solutions of mustard. Marked inflammatory changes occurred in the gastric mucosa as a result of contact with these materials. Seymour Gray and Schindler carefully examined the stomach in a large number of chronically alcoholic persons and came to the conclusion that the prolonged use of alcohol seems to produce chronic gastritis in some persons but has no effect whatever on the stomachs of others, for reasons still unknown.

Numerous authors called attention to the fact that carcinoma of the stomach may simulate chronic diffuse gastritis. Opinion was divided as to the aetiologic role which gastritis plays in the genesis of carcinoma. E. S. Judd, Jr., in a careful pathologic survey of stomachs involved by carcinoma, found significant lesions in the mucosa at a distance from the tumour, suggesting that the entire mucosa is the host to the malignant process. It was his opinion that the mucosal changes commence long before the actual appearance of the carcinoma and that carcinoma develops in a previously damaged stomach, the antecedent injury having been present for a long time. In Judd's material the pathogenesis of carcinoma of the stomach seemed directly related to a disorganized hyperplasia of the mucous cells.

The decade saw general acceptance of the rationale of early feeding in the treatment of bleeding from the gastrointestinal tract. The convalescence of patients who have had massive bleeding from the gastrointestinal tract and who have been treated in this way was materially improved. The time-honoured method of prolonged starvation was all but discarded. Although the fatality statistics accompanying gastroduodenal bleeding varied widely and were often unreliable, it was generally accepted that it is best to treat massive bleeding from this source conservatively, because there are but few instances in which the bleeding does not cease spontaneously. Although there continued to be proponents for early surgical intervention in these cases, the over-all fatality statistics did not seem to be so favourable among patients so treated. Experience would suggest that a single gastroduodenal haemorrhage is rarely fatal, and that in persons of the younger age groups severe bleeding from this source is much less serious than it is in persons more than 50 years old. The liberal use of plasma and whole blood designed to restore the blood volume as

quickly as possible after haemorrhage had much to commend it. It was demonstrated that whole blood administered properly can be employed without increasing the liability to further bleeding. Most workers continued to prefer to transfuse repeatedly small quantities of blood—approximately 250 c.c.—than to use larger amounts. I. J. Wood advocated the continuous massive transfusion of whole blood by the continuous drip method, and thought that this method not only immeasurably shortened the convalescence, but that it could be used advantageously to prepare a patient rapidly for needed abdominal surgery. If the haemoglobin is restored to a nearly normal level in this way, a surgical operation can be performed safely which otherwise would be attended by a prohibitive risk.

Attention was drawn repeatedly to the fact that the blood urea may rise to a high value after massive gastro-duodenal bleeding. There was no consistent agreement as to the cause of this. There are, apparently, several factors which explain it, the most important being the presence of large amounts of blood in the digestive tract and a temporary decrease of renal function because of the diminished flow of blood through the kidney.

Although the most common source of massive bleeding from the digestive tract is a benign duodenal or benign gastric ulcer, the gastroscopist has shown that exsanguinating and even fatal haemorrhage can be caused by gastritis in the absence of any demonstrable associated lesion. Other common causes of severe bleeding are vascular lesions such as varicose veins, tumours of various types such as polyps and hemangiomas and, less often, malignant tumours.

In the treatment of benign ulceration of the stomach and duodenum, one of the sheet anchors is a diet which unfortunately proves to be deficient in essential vitamins. Since this deficient diet often is utilized for extended periods, a chronic state of avitaminosis is certain to exist, and although a frank deficiency state may not be clinically discernible, yet research in this field of metabolism indicated the wisdom of supplying supplementary vitamins in adequate quantity during the time a restricted diet is followed.

Numerous articles appeared during the decade on the problem of the neutralization of gastric acid. The importance of this was obvious when it is recalled that the approach to the treatment of gastroduodenal ulcer through the years had been primarily directed toward ablation of the gastric acid. Frederick Kellogg and S. R. Mettier noted that complete neutralization of the gastric acidity seriously interferes with the absorption of iron from the gastrointestinal tract, thus impeding recovery from an iron-deficiency anaemia. There was general recourse to preparations containing colloidal aluminum hydroxide or magnesium trisilicate in lieu of the time-honoured combinations of sodium bicarbonate, calcium carbonate and magnesium oxide. Colloidal aluminum hydroxide and magnesium trisilicate are not absorbed systemically in significant amounts from the gastrointestinal tract, and as a result they do not cause the serious manifestations of toxicity which may rise during the course of treatment with other

Colloidal preparations of aluminum hydroxide and magnesium trisilicate also proved their worth for persons who have associated renal disease that makes ordinary alkaline therapy prohibitive. Moreover, colloidal aluminum hydroxide lent itself to a particularly useful mode of utilization in that dilute solutions of this substance can be administered continuously by the drip method throughout a

24-hour period. This is accomplished by means of an indwelling nasogastric tube, thus assuring continuous neutralization of the gastric acid and permitting more rapid healing of an ulcer than was formerly possible, and also introducing a significant aid in the medical control of otherwise intractable lesions. Of the two drugs, colloidal aluminum hydroxide would appear to be the more efficient, but it, as well as magnesium trisilicate, has some undesirable features. These undesirable characteristics happily are neutralized by a combination of the two drugs. Colloidal aluminum hydroxide, in addition to its antacid effect, has a multiple mechanism which includes a slight astringent and demulcent property and an absorptive action on toxins; thus its value is enhanced, since it therefore combats three probable major factors in the pathogenesis of peptic ulcer: trauma, acid erosion and infection.

R. Schwenk made a critical review of reports on the histidine treatment of gastroduodenal ulcer. He also treated a series of patients with a histidine preparation. He concluded that histidine does not fulfil any of the requirements for an ulcer remedy, and that it should be disregarded in the therapeusis of ulcer. This observation was in keeping with the experience with this drug generally.

G. F. Dick and C. W. Eisele carried out an interesting observation in a study of 41 patients who had peptic ulcer. Instead of attempting to neutralize the gastric acidity with the antacid preparations generally favoured, they simply fed their patients at hourly intervals. Their data demonstrated that the healing of peptic ulcers would progress satisfactorily without the neutralization of gastric acidity with alkalies and that the speed of recovery achieved by this method compared favourably with that observed in any other type of treatment.

A serious attempt to combat the ulcer-producing factor by ablation of peptic activity was undertaken. S. J. Fogelson and D. E. Shoch suggested the use of a surface active agent such as sodium alkyl sulphate, but it was doubtful that this approach offered anything more than did the time-tried neutralization of the gastric acid which indirectly inactivates peptic activity, anyway.

The introduction of enzymatic hydrolysates of casein gave rise to their use in the treatment of peptic ulcer. The substances rapidly gained favour, but it was exceedingly doubtful that this form of treatment offered any more than did the time-tested modifications of the Sippy regime in which bland feedings frequently are given. These substances lend themselves to a ready means of administering large amounts of available protein, which may be particularly advantageous in some cases in which there have been massive haemorrhage or in which there is an associated state of malnourishment and a low intake of protein.

The surgical treatment of gastroduodenal ulcer was featured by an emphasis on partial gastric resection as a treatment of choice. Periodically there was a suggestion that ablation of the vagal effect would be a more nearly physiologic approach. Asher Winkelstein and A. A. Berg, and later L. R. Dragstedt and his co-workers placed renewed emphasis on vagotomy as a method of treatment. The results that they achieved thereby were so encouraging as to call for a thorough evaluation of the subject.

Carcinoma of the stomach, because of its frequency of occurrence, continued to demand real interest on the part of the gastroenterologist. The major emphasis was on refinements in diagnosis, leading to recognition of the lesion in an earlier stage of its development, thereby enhancing the chance of cure. The gastroscope improved the ability to recognize gastric carcinoma as a small lesion. Repeated

emphasis was given the importance of considering any circumscribed gastric ulcer to be potentially malignant, and to that of recognizing that no clinical sign or laboratory method gives any surety of the accuracy of the diagnosis in any particular case. Radical gastric resection remained, as formerly, the only method of treatment offering any hope of success in carcinoma of the stomach.

Biliary and Pancreatic Systems.—A continued search for a reliable test of hepatic function was manifest in the literature of the decade. Real progress was made in this field, although obviously an all-inclusive test of hepatic function had not yet been found, nor was it likely to be, because of the manifold functions of the liver. One of the most informative aids in the diagnosis of deep jaundice was a reliable method for determination of the patency of the common bile duct. Duodenal intubation had been a useful procedure, but as a method it had serious limitations. C. J. Watson showed that the quantitative estimation of the urinary and fecal output of urobilinogen gives the most reliable index of the patency of the extrahepatic bile ducts. The method is objectionable only because it is cumbersome, unpleasant and time-consuming. A later refinement was less difficult to perform from the standpoint of laboratory technic; it can be done more quickly than the more detailed quantitative determination, and gives a result which to all intents and purposes is as informative.

The introduction of the cephalin-cholesterol flocculation test was a significant addition to diagnostic aids with respect to hepatic disease. This test proved itself of decided value. It is not so much a measure of hepatic function as it is a measure of hepatocellular disease, as compared to some lesion involving the extrahepatic biliary system. Viewed in the light of this fact, it was apparent that one of its greatest fields of usefulness is in assisting in the proper classification of deep, painless jaundice.

Waltman Walters, J. M. McGowan, W. L. Butsch and P. A. Knepper made an important contribution to understanding of the mechanism of biliary colic, particularly in that type in which troublesome attacks of pain are unattended by any demonstrable lesion of the extrahepatic bile ducts. These workers demonstrated that the biliary colic of constipation after removal of the gall bladder was coincident with an increase in intraductal pressure, that the use of morphine often enhanced this and that the most logical drug to use from the standpoint of physiologic effect and clinical result was nitroglycerine. Nitroglycerine was demonstrated to relax the sphincter of Oddi, thus reducing the intraductal pressure and abolishing the pain.

The general use of vitamin K and an understanding of the mechanism by which it abolishes cholemic bleeding was one of the most highly significant advances in the treatment of disease of the liver. Vitamin K is not, however, always completely effective in controlling the haemorrhagic tendency in severe disease of the liver. Parenchymatous hepatic damage may be so severe as to prevent utilization of the vitamin in the manufacture of prothrombin, in which case even large amounts of vitamin K will be of no help in controlling the bleeding tendency.

Knowledge of the pathologic physiology of the liver was advanced by the increasing use of aspiration biopsy. Kaj Roholm and P. Iversen studied 26 cases of so-called catarrhal jaundice by this method. They found diffuse hepatitis, with destruction of the trabecular structure of the liver cells. C. J. Tripoli and D. E. Fader described a modification of a punch biopsy needle which permits the taking of specimens of hepatic tissue for biopsy without suction or maceration of tissues. There was considerable interest in this field, but the method did not receive gen-

eral acceptance, because it was associated with a definite risk which in some hands had approached that of laparotomy for the same purpose. It would seem that the procedure could be more valuable and could be more safely performed if it were combined with the more direct control which associated peritoneoscopy would afford.

The treatment of cirrhosis of the liver changed considerably during the decade. Treatment devoted principally to elimination of ascites by the use of mercurial diuretics, restriction of fluids and purgation was largely abandoned, and reliance was placed chiefly on a diet high in carbohydrate and protein, together with the administration of large doses of vitamin supplements. A. J. Patek, Jr. and Joseph Post said that this type of treatment was of value. In their series, the patients so treated survived for increased periods and exhibited signs of bodily improvement and presumptive evidence of arrest of the disease. Choline was suggested as an adjuvant in the treatment of cirrhosis. The value of choline was questioned by some, but it would appear to have some value in the hypertrophic phase of the disease, particularly where there has been considerable fatty replacement of the liver cells.

The question of the aetiologic agent in hepatocellular disease came into sharp focus because of the experience gained in World War II. The transmission of acute hepatitis by yellow-fever vaccine, in the preparation of which human serum was used, indicated that the use of whole blood and its products is attended by definite risk. The frequent occurrence of severe, often fatal hepatitis, among military personnel after the administration of human serum verified the transmissibility of the infective agent of hepatitis. It was believed that the causative agent is a virus, and there was evidence that the agent also may be transmitted via the human excreta and by droplet infection. The highly virulent course of the disease which follows the entrance of the infective agent by the intravenous route led to the labelling of hepatitis which follows the administration of whole blood or blood products as "homologous serum hepatitis" and to considering it as a separate entity, when compared with ordinary infectious hepatitis. Whether or not the condition actually is a separate disease, or whether the minor differences between homologous serum hepatitis and ordinary infectious hepatitis are the results of the difference in the portal of entry of the infective agent, had not yet been definitely established at the end of the decade.

M. W. Comfort and R. M. Hoyne called attention to an interesting entity which they chose to label "constitutional hepatic dysfunction." It is a condition of chronic jaundice in which no demonstrable impairment of hepatic function exists. The condition may be congenital or acquired, and probably is due to an inborn deficiency of the liver cells.

An adequate test for evaluation of the function of external secretion of the pancreas had long been awaited. Therefore, the development of a preparation of secretin, as reported by Gunnar Ågren, Henrik Lagerlöf and Hilding Berglund, which could be safely used, and which had a definite stimulating effect on the external secretion of the pancreas was highly significant. It is true that values for serum amylase and serum lipase had been of proved help in the estimation of pancreatic disease, but they are useful only during acute transient disease of the pancreas. No adequate measure of the function of the pancreas involved in a chronic disease process had been available heretofore.

In the field of treatment of pancreatic disease two trends

were apparent. The first was one of conservatism in the handling of inflammatory disease of the pancreas. The second was a willingness on the part of the surgeon to undertake radical resection of the pancreas for malignant disease and for chronic, long-standing, disabling, painful benign disease, such as extensive formation of stones.

Intestinal Tract.—The decade 1937-46 witnessed the development of a small-calibre double-lumened tube as a diagnostic and therapeutic aid in cases of obstructive lesions of the intestine. This tube found its greatest value in lesions involving the small intestine. T. G. Miller, W. O. Abbott and W. G. Karr demonstrated the ease with which the tube could be introduced and announced their willingness to perform intubation for patients with unexplained abdominal pain, abdominal distension, ulcerative colitis, obstruction of the common bile duct and intestinal obstruction arising from carcinoma of the cecum. Later, O. H. Wangensteen and his associates, R. J. Noer and C. G. Johnston and D. M. Willson reported experience attesting to the efficiency of the intubation method in handling acute intestinal obstruction. The tube was much favoured in the immediate postoperative period when surgical procedures have been performed on the intestine, since it not only acts as a safeguard in combating postoperative ileus, but also is of use for feeding purposes during the convalescent period.

Ross Golden emphasized the importance of diarrhoea as a symptom of disease involving the small bowel, and recommended roentgenologic examination of the small bowel in all cases of otherwise unexplained diarrhoea.

Numerous articles appeared emphasizing that Giardia lamblia, formerly considered a nonpathogen, is an important cause of morbidity, being not only a cause of protracted diarrhoea, but also an aetiologic factor in vague abdominal distress of various kinds. A simple, safe and effective means of eradication of the parasite became available in the form of atabrine.

Some of the most practically helpful advances observed in the care of intestinal disturbances centred about the development of new drugs. Prostigmine came to occupy an assured place in the effective control of abdominal distension. Papaverine was demonstrated to be of value in the control of painful intestinal spasm. Perhaps the most helpful aids in the care of intestinal disease came from the various sulfonamides. Sulfaguanidine, sulfasuxidine and sulfathalidine proved their worth as intestinal antiseptic agents, and came to occupy an assured place in the preoperative preparation of intestinal lesions and in the control of certain of the infectious diarrhoeas. The sulfonamides generally, and later the antibiotics, vastly improved the prognosis of such severe complications as perforation of acute appendicitis, or the rupture of any other abdominal viscus.

As was to be expected, World War II focused attention on diarrhoeal conditions, particularly those caused by the bacillary organisms. In this group of diseases the sulfonamides proved particularly useful.

J. S. Atwater and J. A. Bargen, studying a series of specimens obtained at necropsy, were able to trace the pathogenesis of intestinal polyps from the earliest epithelial change to frank carcinoma, emphasizing once again that the word "benign" should not be used in describing an intestinal polyp, but that the lesion should be considered, as it truly is, one stage in the pathogenesis of carcinoma, which eventually will definitely develop.

Allen, Terry de la Mesa

Allen (1888—), U.S. army officer, was born April 1, 1888, at Ft. Douglas, Utah. After graduating from the U.S. military academy at West Point in 1911, he studied at the Catholic University of America, where he received his A.B. degree in 1912. He entered the U.S. army the same year, becoming a second lieutenant in the cavalry. He served with the A.E.F. in World War I, taking part in various U.S. offensives. Between the two World Wars he studied at several military institutions, including the Army War college. Allen, who was a brigadier general at the time of the Pearl Harbor attack, was made a major general in 1942. He assumed command of the 1st infantry division which participated in the Tunisian and Sicilian campaigns.

Ordered back to the United States in Sept. 1943, he was put in command of the 104th division. Returning to Europe, Allen led the 104th ("Timber Wolves") division in the fighting in the Netherlands in late 1944 in support of the right wing of the Canadian 1st army attacking

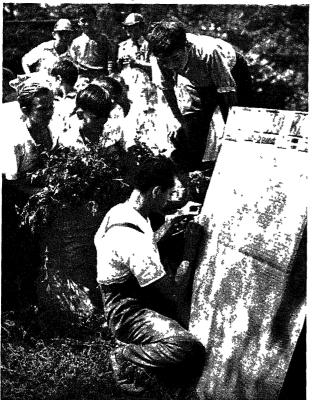

Antwerp. The 104th had fought its way into Germany at the end of the war. Gen. Allen returned to the U.S. in July 1945 and was slated for redeployment to the Pacific. After V-J day, however, he retired from the army (Nov. 21, 1945).

Allergy

Important questions regarding the mechanism of the allergic reaction were clarified during the ten years 1937–46. E. W. Phillips observed in 1939 that allergic persons required a period of three consecutive years of exposure to sugar-beet pollen before developing hay fever symptoms, and that five years of exposure to Johnson grass smut was required before allergy developed.

Chemical studies by A. Stull and his co-workers led to a differentiation of at least two antigens in ragweed pollen. Sensitive patients varied in their skin reactivity to each of the isolated fractions. Normal persons whose skin was temporarily sensitized with serum from ragweed patients likewise varied in their response to the two fractions. This indicated that serum from sensitive patients had different antibodies which corresponded to the isolated pollen fractions. By a different approach, R. Hecht and his coworkers, followed by M. M. Mosko and his associates, showed that the substances in ragweed pollen causing symptoms (allergens) could be differentiated on the basis of their molecular size. The portion consisting of small molecules was unaltered by boiling, and produced practically as strong skin reactions after heating as the whole untreated ragweed extract. This skin reactive portion was apparently only a partial antigen, as it was incapable of sensitizing rabbits. The second portion, consisting of the large molecular elements, was thermolabile and capable of producing immunologic reactions in the rabbit.

Ragweed harvesters at Cleveland, O., watching their competitive scoreboard. Aimed at relieving distress to hay fever victims in the area, the annual harvest ended with a party and honours for the highest scorers

Significant studies were made regarding antibodies in allergy. Stull and his co-workers showed that reagin, the skin sensitizing antibody, was associated with the globulin fraction of human serum. Most of the immunologic work in allergy dealt with the properties of a newly discovered antibody. This was first briefly noted by R. A. Cooke and his co-workers in 1935. The same author and coworkers established in later work that this new antibody "blocked" the reaction between serum used for sensitizing normal skin and the specific antigen. This "blocking antibody" was absent in untreated patients; it developed after pollen injections. M. H. Loveless and others in numerous contributions worked out the other important characteristics of this antibody. She found that in contradistinction to reagin, the new antibody resisted heating and could be produced in normal as well as allergic persons following pollen injections. Loveless later showed that the concentration of the blocking antibody in treated patients was generally proportional to the degree of their improvement. This relationship was questioned by the work of others, notably M. A. Scully and F. M. Rackemann. The report by F. W. Wittich of typical, spontaneous, seasonal hay fever in a dog gave workers an experimental approach in an animal which might ultimately help to resolve some of these contradictory reports.

Many new causes for allergic symptoms were described during the decade. Only the most important can be mentioned. The discovery of the prominence of air-borne moulds in respiratory and to some extent in skin allergy headed this group of contributions. The contributions of T. B. Bernstein and S. M. Feinberg, following the work of O. C. Durham and many others, emphasized that the status of moulds as causes of allergy was almost as important as that of ragweed pollen.

Emanations and bites from insects were found to be not uncommon as causes of allergy. Reports incriminated May flies, houseflies, mosquitoes, bees, wasps, moths and many other insects.

Simple chemicals as causes of allergy led to clarification of obscure and increasingly important allergic agents. Urticaria caused by aliphatic aldehydes (B. Z. Rappaport and M. M. Hoffman), hay fever and asthma resulting from chloramine T, and eczema from many contact substances were among the many causes described.

The scope of allergy was broadened by the discovery that certain conditions of obscure origin were occasionally caused by sensitivity. Thrombopenic purpura, a blood disturbance characterized by frequent internal haemorrhages caused by a deficiency of blood platelets, was shown by L. O. Dutton in 1938 to be due in some cases to food allergy. In 1937 T. L. Squier and F. W. Madison had reported other cases caused by drug allergy. S. F. Hampton reported one case of Henoch's purpura, another haemorrhagic condition, caused by food sensitivity. J. Harkavy concluded, from experiments on rats, that Buerger's disease, an illness in which small blood vessels become obliterated, was due to tobacco sensitivity.

An outstanding contribution toward the treatment of allergy was the development of the antihistamine compounds. By opposing the action of histamine, which is presumably an important cause of allergic symptoms, these newly developed drugs often relieved but did not cure. The compounds were first studied in France by A. M. Staub and D. Bovet. The drug they reported relieved anaphylaxis in animals but was too toxic for humans. Later, still in France, B. N. Halpern evolved much less

toxic compounds which could be used effectively in humans to relieve allergy. A number of antihistamine compounds were later used, including benadryl and pyrabenzamine.

Useful therapeutic contributions resulted from modification of pollen in various ways to slow its absorption. This was done either through chemical methods (G. E. Rockwell; H. L. Naterman) or by the addition of a substance like gelatin (W. C. Spain and associates). The use of gelatin or oil with epinephrin solution to slow its absorption was another effective contribution in the therapy of allergy.

Allied Commission on Reparations

See REPARATIONS (WORLD WAR II).

Allied Control Commission for Austria

Early in June 1945, following the cessation of hostilities in Austria (q.v.), a joint British, French and U.S. reconnaissance party was sent into Vienna to survey and discuss the situation there with the soviet commander. On the basis of this party's report, the European Advisory commission in London reached agreement on the control machinery to be used by the four occupying powers—Great Britain, France, the U.S.S.R. and the United States. On July 6, 1945, command of the U.S. forces in Austria was assumed by Gen. Mark W. Clark, and late in August, the four powers established their respective headquarters in Vienna and Austria came under quadripartite control.

An Allied commission was organized as follows: (1) an Allied council, consisting of one high commissioner of each power; (2) an executive committee, consisting of a senior representative of each of the high commissioners; (3) staffs of each of the four powers, organized into divisions matching the main departments of the Austrian federal government; and (4) an Allied secretariat. Members of the commission might be either civilian or military, but the commanders in chief and their military deputies habitually filled the Allied council and executive committee posts. Provision was also made that political advisers of the respective high commissioners might attend the council meetings.

The Allied council, at its first meeting on Sept. 11, 1945, announced to the Austrian people that it had assumed supreme authority in Austria and that it would be guided by the Moscow declaration, in which the governments of the United Nations declared their intention to see restored a free, independent and democratic Austria.

In its deliberations, the Allied commission was obliged

to discuss all questions in at least four languages, to reconcile five different conceptions of "democracy" and to reach decisions by unanimous agreement. Despite these handicaps, considerable progress was made in many phases of reconstruction and rehabilitation. Complete severance of Austria from Germany in political and administrative matters was effected; the work of denazification and demilitarization was well organized, with satisfactory results attained; public transportation facilities were restored, in some cases to prewar levels; standards of housing, feeding, clothing, education and public health were materially raised; agriculture and industry were revived; and the currency was stabilized and inflation prevented.

On June 28, 1946, a new control agreement for Austria was signed and put into effect by the Four Powers. This agreement extended the authority of the Austrian government fully throughout Austria, subject only to certain reservations concerning matters in which the occupying powers had a particular and overriding interest, and to such special instructions as the Allied commission might give in other matters.

Adoption of this agreement was the most important step yet taken toward the restoration of a free and independent Austria and was hailed enthusiastically by the Austrian people.

For the first time, the Austrian government, which had come into being as a result of the democratic elections held in Nov. 1945, was free to function without the necessity of having all its actions approved by the occupying powers.

At the close of 1946, four major problems still confronted the Allied commission: (1) maintenance of an adequate food supply until the 1947 harvest, without benefit of further United Nations Relief and Rehabilitation administration aid; (2) disposition by repatriation or resettlement of some 230,000 displaced persons remaining in Austria; (3) establishment of freedom of navigation on the Danube; and (4) reaching of an agreement between the soviet, on the one hand, and the other three powers, on the other hand, with regard to the nature and extent of reparations to be demanded of Austria under the Potsdam agreement. The soviet unilateral definition of German external assets was a matter of grave concern both to the other powers and to the Austrian government, for the reason that complete implementation of reparations in accordance with this definition would prohibit the rehabilitation of the Austrian economy and set up a serious obstacle to the achievement of the economic unity of Austria.

(See also Allied Control Council for Germany; Allied Military Government; European Advisory Commission.) (M. Ck.)

Allied Control Council for Germany

The Allied Control authority, located in the city of Berlin, was organized by the four occupying powers in Germany for the period during which the basic requirements of unconditional surrender were to be carried out. It was established in conformity with the protocol "Agreement on the Control Machinery for Germany" as prepared by the European Advisory commission and ratified by the member governments of the United States, United Kingdom, France and the U.S.S.R. represented thereon. The highest echelon of the Allied Control authority was the Allied Control council, composed of the four commanders in chief of the four zones of occupation of Germany and established to ensure uniformity of action by the commanders in chief in their respective zones, to deal

with questions affecting Germany as a whole, and to control such German central administrative agencies as might be established. This body met three times monthly after July 31, 1945. Its chairmanship was held in rotation by each of its members in the order United States, United Kingdom, France and the U.S.S.R.

The co-ordinating committee, the next subordinate level of the control authority, was composed of a representative of each of the four commanders in chief, in general the deputy military governors. The functions of this committee, acting on behalf of the control council and through the control staff, included carrying out the decisions of the control council, co-ordinating current problems, preliminary examination of all questions submitted to the control council, and the day-to-day supervision and control of activities of such German central agencies as might be established. The co-ordinating committee met six times monthly after Aug. 11, 1945, with the same procedure for chairmanship as the control council.

The control staff, the third echelon of the control authority, was composed of 12 directorates and 1 commission, each being quadripartite.

The military directorate was concerned primarily with the disbanding of the German wehrmacht, its disarmament, disposition of arms, ammunition and equipment. The naval directorate functions were similar to those of the military directorate insofar as German naval matters were concerned. The air directorate acted on matters affecting the former luftwaffe and air traffic, military and civilian, in Germany.

The transport directorate dealt with all matters involving motor, rail and water transportation, including questions involving inland water transport and questions of international transport involving Germany.

The political directorate had a dual function of supervising the political activities within Germany and serving as the office of contact between the Allied Control authority and foreign nations. The economic directorate, the largest directorate, covered the whole broad field of matters pertaining to the economy of Germany, including the level of industry plan, price control and control of scientific research and development. The finance directorate was made responsible for the fiscal and price control policy of the Allies.

Other directorates included the following: reparations, deliveries and restitution directorate, performing the functions indicated in its title; internal affairs and communications directorate, concerned with civil administration, public safety, public health and welfare, and organization and operation of the communications system within the four zones, the latter including postal problems; legal directorate, with the responsibility of supervising the legal structure of Germany for the control authority; manpower directorate, concerned with matters affecting trade union organization, employment, unemployment compensation policy, work codes and general wage policy.

The prisoner of war and displaced persons directorate had responsibility for prisoners of war, limited generally to co-ordination of movement among the four zones of Germany of discharged prisoners of war. It advised the control council on matters affecting the return to their native countries of the numerous labourers brought to Germany to support the reich's war effort, and other displaced persons. It was concerned also with the migration into Germany of such minority groups as were expelled from other countries.

The German external property commission was formed after the original agreement. In it were vested, by control

council law, titles to German external assets.

For the administration of the greater Berlin area, garrisoned jointly by forces of the four occupying powers, the Allied Control authority established the Allied Kommandatura, composed of the four commanders in chief of the four national sectors of Berlin.

The Allied Control authority was serviced by the Allied secretariat and the administrative bureau. All discussions throughout all echelons of the control authority were conducted in the three official languages—English, French and Russian. For convenience, particularly in matters of legislation, German translations of documents were accepted but had no official status. (See also Allied Control Commission for Austria; Allied Military Government; European Advisory Commission.)

Allied Control Organization for Japan

On Sept. 2, 1945, on the U.S.S. "Missouri" anchored in Tokyo bay, General of the Army Douglas MacArthur, the supreme commander for the Allied Powers, accepted the surrender of Japan for the United States, the Republic of China, the United Kingdom and the Union of Soviet Socialist Republics, and in the interests of the other United Nations at war with Japan. The instrument of surrender was also signed by representatives of the United States, the Republic of China, the United Kingdom, the Union of Soviet Socialist Republics, the commonwealth of Australia, the dominion of Canada, the provisional government of the French Republic, the kingdom of the Netherlands and the dominion of New Zealand.

The responsibility for achieving the ultimate objectives of the United Nations with respect to Japan—the fostering of conditions which would give the greatest possible assurance that Japan would not again become a menace to the peace and security of the world and which would permit it eventual admission as a responsible and peaceful member of the family of nations—lay with three authorities: the supreme commander for the Allied Powers, the Far Eastern commission, and the Allied Council for Japan.

On Aug. 14, 1945, the same day that Japan accepted the terms of the Potsdam declaration, General MacArthur was designated the supreme commander for the Allied Powers. On the grounds that Allied relations with Japan did not rest on a contractual basis, but on unconditional surrender, the authority of the emperor and the Japanese government to rule the state was subordinated to the authority of the supreme commander for the Allied Powers. He became the sole executive authority for the Allied Powers and exercised his authority through the Japanese governmental machinery and agencies to the extent that this arrangement satisfactorily furthered Allied objectives.

For his guidance, General MacArthur was sent by radio on Aug. 29 and, after approval by the president, by messenger on Sept. 6, 1945, a statement of U.S. government policy entitled "U.S. Initial Post-Surrender Policy for Japan," which was prepared jointly by a committee composed of representatives of the department of state, the war department and department of the navy and dealt with such subjects as military occupation, relationship of Allied authority to the Japanese government, disarmament and demobilization, war criminals, encouragement of desire for individual liberties and democratic processes, economic de-

militarization, resumption of peaceful economic activity, and also provided for the participation in the occupation of Japan of the forces of other nations that had taken a leading part in the war against Japan. In accordance with this provision, U.S. forces in Japan were joined by British commonwealth forces during the first three months of 1946.

As a means of co-ordinating the methods of consultation with other countries interested in the occupation of Japan, the U.S. government on Aug. 21, 1945, invited the governments of China, the United Kingdom and the soviet union to agree to the establishment of a Far Eastern Advisory commission to be composed of the four major Allies adhering to the Moscow declaration of Oct. 30, 1943, and other United Nations with territories in the far east. The terms of reference of the Far Eastern Advisory commission provided that it should be responsible for making recommendations to the participating governments on policy matters connected with the surrender of Japan and on the steps necessary and the machinery required to ensure the strict compliance by Japan with the provisions of the instrument of surrender. The United Kingdom, China, Australia, France, Canada, India, the Netherlands, New Zealand and the Philippines accepted the U.S. proposal to join the Far Eastern Advisory commission, but as the soviet union refused to join the work of the commission before a control council, closely resembling the control council for Germany, was established for Japan, it did not participate in the activities of the Far Eastern Advisory commission.

However, an agreement was reached at Moscow on Dec. 27, 1945, by the foreign ministers of the United States, Great Britain and the soviet union, with the concurrence of China, for the establishment of a Far Eastern commission, composed of the representatives of the soviet union, United Kingdom, United States, China, France, the Netherlands, Canada, Australia, New Zealand, India and the Philippine commonwealth. The Far Eastern commission was formed as a policy-making body with authority (1) "to formulate the policies, principles, and standards in conformity with which the fulfilment by Japan of its obligations under the terms of surrender may be accomplished"; (2) "to review, on the request of any member, any directive issued to the supreme commander for the Allied Powers or any action taken by the supreme commander involving policy decision within the jurisdiction of the commission"; and (3) "to consider such other matters as may be assigned to it by agreement among the participating governments...."

Under the terms of reference of the Far Eastern commission, the supreme commander was charged with the implementation of the directives prepared by the U.S. government expressing the policy decisions of the commission which were dispatched to him through the appropriate U.S. government agency. However, the U.S. government was permitted to issue interim directives to the supreme commander pending action by the commission whenever urgent matters arose not covered by policies already formulated by the commission, provided that any directives dealing with fundamental changes in the Japanese constitutional structure or in the regime of control, or dealing with a change in the Japanese government as a whole were issued only following consultation and following the attainment of agreement in the Far Eastern commission. The first meeting of the Far Eastern commission was held in Washington, D.C., on Feb. 26, 1946.

The three governments also agreed, with the concurrence of China, in the establishment in Tokyo of an Allied

Council for Japan to be composed of the supreme commander as chairman, a United States member, a Union of Soviet Socialist Republics member, a Chinese member and a member representing jointly the United Kingdom, Australia, New Zealand and India. The purpose of the council was to consult with and advise the supreme commander in regard to the implementation of the terms of surrender, the occupation and control of Japan.

Although the terms of reference of the Allied council provided that the supreme commander would consult and advise with the council in advance of the issuance of orders on matters of substance, circumstances permitting, he was the sole executive authority for the Allied Powers in Japan, and in all cases action was to be carried out under and through him. He was to issue all orders for the implementation of the terms of surrender, the occupation and control of Japan, and supplementary directives. If any disagreement arose in the council regarding the implementation of a policy decision of the Far Eastern commission upon any question dealing with fundamental changes in the Japanese constitutional structure or in the regime of control, or dealing with a change in the Japanese government as a whole, the supreme commander was to withhold action pending clarification of its decision by the Far Eastern commission. However, when necessary, the supreme commander, after appropriate consultation with the council, could change individual ministers or fill vacancies. The first meeting of the Allied council was held April 4, 1946, in Tokyo. (See also Allied Military Government; JAPAN.) (J. H. Hc)

Allied Military Government

As defined by the United States war department, civil affairs-military government encompassed all powers exercised by the military commander with respect to the civilian population in liberated, friendly or axis territory during World War II and the postwar period. "Military government" was that established and maintained by the military commander in occupied axis territory prior to its return to the independent authority of the indigenous government and the relinquishment of control by him, or in liberated or friendly territory where no government was recognized by treaty, agreement or course of action as having authority independent of the military commander. "Civil affairs" was the relationship entered into, and the responsibility assumed by a military commander with respect to the government and inhabitants of liberated or friendly territory in which an indigenous government was recognized by treaty, agreement or course of action as having authority independent of the military commander.

Among the powers and responsibilities which might be assumed by the military authorities were the preparation and issuance of proclamations and regulations for civilian populations; the establishment of military courts and the supervision of the indigenous system of justice and the trial and punishment of conventional war criminals (the trial and punishment of major war criminals was conducted in accordance with directives from higher authority); the supervision and control of the civilian economy, including planning for and procural of necessary military supplies to meet minimum civilian requirements; the care, control and repatriation of displaced persons and refugees; the reactivation and supervision of normal functions of civil government such as finance, industry and commerce, food and agriculture, education, labour, public safety, public health and welfare, prisons, religion, social organizations, public information (including the reorienta-

Allied military government officials supervised German civilians at Bruehl as they began to dig out the ruins left by Allied bombing raids in 1945

tion of axis thinking, press and radio, publications, films, theatres, music and instructional materials), transportation, communications, property control, archives, arts and monuments, censorship of civilian communications; salvage of materials for civilian use; and the control of restitution and reparations. (Restitution and reparations were handled in accordance with direction from higher authority—subsequent to combat phase of operations.) Hereafter in this article, the term "civil affairs" will be used, for the sake of brevity, to include both civil affairs and military government.

The inevitability of military responsibility for civil affairs was a proved fact. In its relatively short existence, the U.S. army had participated in 25 to 30 military occupations. In the Mexican, Civil and Spanish-American Wars, civil affairs was one of the major responsibilities of the military commanders. A large part of the success of the occupations of the Philippines and Cuba resulted from proper regard for and actions of military governors; Burgoyne's failure at Saratoga, and many of the failures of the Civil War could be traced to improper civil affairs actions.

Personnel and Training.-The Rhineland experience of World War I caused the U.S. army, in the '20s and '30s, to train and plan for civil affairs. Between World War I and World War II, civil affairs instruction was given at the War college; provision was made for civil affairs organizations and operations in the war plans of the general staff. By Dec. 7, 1941, the army had published a civil affairs manual which contained the principles learned and civil affairs operational policy evolved from past experiences. In addition, there was a small group of officers who were trained in this special field. Thereafter the army's School of Military Government was established at the University of Virginia, Charlottesville, Va., and the first class graduated in Sept. 1942. At one time during World War II, civil affairs training was given in army and navy schools located at 12 of the nation's leading universities. By the time hostilities had ceased, more than 7,000 officers had received this special training. Following cessation of hostilities the training program was curtailed; thereafter replacements only were trained. The 7,000 trained was the number estimated to be required during hostilities. On defeat of the axis and occupation of all areas, additional personnel requirements were to be met by transfers from other units of the army. As combat personnel needs decreased early in 1945, officers whose

civilian experience qualified them for government duty were transferred from combat units.

In the fall of 1945, there were approximately 30,000 U.S. military personnel engaged in civil affairs in occupied areas. Also, following defeat of the axis, the transition from all military personnel to a combination of civilian and military personnel began. To make the control of the axis areas more representative of the United States, plans to replace some of the military with civilian personnel as rapidly as security considerations permitted had been approved. In the summer of 1946, 15,000 U.S. nationals were engaged in civil affairs activities in occupied areas, of whom 8,000 were military and 7,000 civilian.

Civil Affairs Organization.—In the winter of 1942–43, while the North African operation was under way, national and international policy-making bodies were established in Washington to formulate U.S. and Allied civil affairs policy to be executed by military forces in friendly and enemy areas. The principal U.S. body operated under the joint chiefs of staff and the international body under the combined chiefs of staff. For the most part, this civil affairs policy had to do with political, economic and social questions, but during hostilities there were always military implications which were often of vital concern. The basic political, economic and social policy questions were co-ordinated with the departments primarily responsible for such matters in the United States and in the other Allied and associated powers. But because of the military

Parisian children eating at a communal restaurant set up by Allied relief authorities after the French capital's liberation in 1944

implications and because of the primary responsibility of the war and navy departments to support and provide policy guidance to commanders overseas, the joint and combined chiefs of staff controlled the machinery charged with the co-ordination of the civil affairs policy and its dispatch to commanders overseas. Lives of troops and success of military missions often depended on timeliness of policy direction. Success of the military mission was often influenced by exchange rates, supplies for civilians, treatment of displaced persons or availability of local materials. In this situation the military took the lead in supplying policy guidance to overseas commanders. Allied policy was formed at the military level, but only after consultation and guidance from the civilian agencies charged with primary responsibility in the foreign policy field.

In the year following cessation of hostilities, the diplomatic agents of the Allied governments assumed leadership in the operation of the machinery established to formulate foreign policy. Military implications became less and less a consideration; long-range political, social and economic objectives were substituted for those concerned with defeat of the enemy armed forces. As the war and navy departments' roles were restricted more and more to executive matters, the department of state became more active. A new committee made up of state, war and navy representatives assumed much of what had formerly been the work of the joint and combined chiefs of staff. In the spring of 1946, a new assistant secretaryship for occupied areas was established in the department of state.

With the cessation of hostilities, another policy-making class of agency, the Allied control bodies in occupied areas, came into very active operation. Prior to that time, central civil affairs missions and control bodies had operated, but it was not until the Allied control body was established in Germany, and later in Austria, that much of the policy making was shifted to the occupied areas. Restoration of free movement and communication between the capitals of the Allies and the occupied areas made this delegation desirable. Subordinate policy matters, which were tied closely to the task of execution, could better be discussed on the ground between those directly charged with execution. These national military commanders, who served both as commanders of their troops and as representatives of their nations on the control bodies, attempted to produce, vis-à-vis their military opposite numbers, a common occupation policy for execution of agreements of the heads of Allied governments or their diplomatic agents. These bodies were of extreme importance in Germany and Austria. For occupation purposes, each of those two countries was divided into four zones, and occupation responsibility for the two countries was assumed on a zonal basis by the four powers. The four-power Allied control bodies were to provide the central administration. When agreement was not possible, national policy was executed in the respective national zones of the occupied areas.

The organization and responsibility for Japan differed from the European pattern. Japan was not divided into zones, and control was united in the supreme commander for the Allied powers, who was also the U.S. commander. Instructions to him were issued through U.S. military channels. In addition, there sat in Tokyo a four-power council which advised the supreme commander; and in Washington an 11-power commission which formulated policies for the control of Japan. In situations where this commission had not formulated a policy, the United States, acting unilaterally, might issue interim directives.

Korea was occupied in the north by the U.S.S.R. and

in the south by the U.S. forces, each area being administered separately. Under the provisions of the agreement reached by the United States, United Kingdom, China and the U.S.S.R. in Moscow in Dec. 1945, a joint U.S. Soviet commission of military representatives of the two powers was formed in the spring of 1946, to co-ordinate military administration and, after consultation with the Korean democratic parties and social organizations, to assist in the formation of a representative provisional government for the whole of the country. This commission was not able to reach the detailed agreements necessary.

The civil affairs objectives of the United States were to control and accord to civilian populations treatment provided for under the rules of international law; to obtain resources and services in aid of the military mission; and, in a liberated area, to encourage the political rebirth of the nation so that it might become an active ally in the prosecution of the war, and, in an enemy area, to rid it of the immediate political and economic influences which had brought on the war. The broad mission was a mixture of diplomatic and executive responsibilities. Also, the political and economic objectives in enemy areas were long-term programs reaching beyond the hostilities phase of war. The diplomatic mission was a primary responsibility of the heads of the Allied governments and their diplomatic agents; the executive mission was a primary responsibility of the military which controlled the troops and supplies only through which the objectives could be

Areas of Allied Disagreement.—Prior to the outbreak of World War II, most civilized nations of the world had reached substantial agreement on the standards of treatment to be accorded civilian populations by military forces, the extent of governmental control to be exercised by military commanders and the permissible extent of exploitation of local resources and services by military forces. Treaties and conventions adhered to or binding on the United States had been codified in the U.S. army's Field Manual 27-10.

Determination of and (in the case of allies) agreement on political and economic objectives could never, because of their very nature, be made in advance of war and identification of allies and enemies. Long before cessation of hostilities in World War II, the Allies were in substantial agreement on the basic objectives. There was agreement among the Allies that the political and economic life of the axis nations should be controlled through complete occupation by military forces, and that this control should be gradually relaxed and finally removed only after these axis nations had demonstrated their right to become members of the community of democratic and peace-loving nations. Further, there was agreement to demilitarize the axis nations, to purge from government and business the nazis in Germany and the ultranationalists in Japan, to exact reasonable reparations, to punish war criminals and to democratize. Lack of agreement among the Allies pertained chiefly to matters of interpretation and translation of desires into effective action.

The Allies rapidly reached agreement to destroy the military machines of the axis nations and to demobilize the personnel. But demilitarization included destruction of the enemy war potential. Destruction of particular plants or groups of plants and the question of the level of production of a particular product demonstrated from the outset that while the Allies were united in their desire for defeat of the axis' armed forces, their interests in the axis' economy of the future differed radically.

In Germany, the most hated nazis, those personally responsible for the war and those who had held high positions of authority in government and business, had abandoned their positions of authority when the Allies arrived. But several hundred thousand persons who occupied positions of less authority, who felt they had a chance of survival and had remained, constituted problems requiring policy decisions. Agreements on categories to be removed were required. Here again, in the details of execution of policy, the Allies were not in complete agreement. The United States went much further than its Allies in disqualifying persons for office in government and business because of political affiliations or collaboration. In the U.S. zone of Germany persons labelled nazis could not be employed in government or business in any capacity higher than that of labourer.

Reparations was another of the objectives on which there was not complete agreement. All were agreed that axis nations should respond for the loss caused by the war insofar as it was feasible. It was not surprising, however, that the amount of feasible reparations should be disputed among Allies whose individual and personal interests in reparations varied between great extremes. Some of the Allies entered the war with a highly developed industrial plant and came out of the war with that plant not only undamaged but greatly expanded. Others had had an industrial plant largely undeveloped before the war, and during the war even that had suffered much damage. In this situation, regard for reparations varied from a positive desire not to accept axis goods and plants, except for research purposes, to a feeling of absolute dependence on axis goods and plants to restore war losses and to advance the development of home industry.

The variation in opinion pertaining to reparations was no greater than that pertaining to democratization. Each of the Allies desired to establish democratic governments in the axis nations, but they did not agree on a definition of democracy. To some, democracy meant free choice of government representatives by the majority of the electorate who would retain a right to establish and maintain opposing parties as agencies in the making of this choice; and following elections, the representatives would continue to be responsible to the people who would retain, under constitutional guarantees, the right to oppose these representatives in succeeding elections. To others, democracy had a quite different meaning. To them, it was government for the people but not by the people. Officials were responsible to the government and not to the people; no right to be in opposition or to have elections in the future was guaranteed by the constitution. As a guarantee of its future security, each of the Allies desired to establish in neighbouring areas governments with ideals and forms similar to its own.

One of the declared war aims of the Allies was the punishment of war criminals. This aim was proclaimed in the Moscow declaration, reaffirmed at Potsdam and internationally implemented by the London agreement of Aug. 8, 1945, and by a policy agreement of the Far Eastern commission which was formulated in the Articles of the International Military Tribunal for the Far East. President Roosevelt and congress made many statements expressing determination that the program for the prosecution of war criminals would be vigorous and unrelenting. There was precedent in U.S. history for such prosecution; Captain Wirz, commandant of Libby prison, Andersonville, Ga., was tried and hanged in 1865 for killing prisoners

without justification by the laws of war.

German zonal administration became the most vexing of all subjects of disagreement among the Allies. The Potsdam declaration provided for administration of Germany as a political and economic unit. Economically and administratively, the four zones of Germany were interdependent. The four zones were established to determine only troop occupation responsibility of the several Allies; insofar as these lines were used to establish administrative and economic barriers, they impeded attainment of almost all the basic objectives of the Allies. In the summer of 1946, the United States announced at Stuttgart its determination to provide for integration of the administration of Germany by the four powers insofar as possible, and invited all of its Allies to join with it. It appeared that only the British would join the United States in integrating the administration of the zones.

The diplomatic difficulties of the Allies in Germany were reflected in Austria and Korea. The same basic differences existed in Japan, but that country was not divided into zones. There, execution of policy was under the supreme commander of the Allied powers, and administration did not wait on diplomatic agreement among the Allies.

Mission of the U.S. Armed Forces.—In spite of the slow rate at which agreement among the Allies had been reached in negotiations between the heads of government or their diplomatic agents, much was accomplished by the military forces toward attainment of the principal objectives both during and after hostilities.

The first objective, accord of humane and fair treatment to civilian populations, was attained simultaneously with occupation of an area. Civilian conditions improved as order was restored and as shipping for civilian supplies became available. Attainment of the first objective made realization of the second possible. Restoration of order and provision of supplies brought to the military forces the local goods and services. The political objectives were not always as readily attained. However, even in this controversial field, rapid progress was made. Within a relatively short time after the invasion of North Africa, there was a government at least tentatively acceptable to those concerned. Before the next step was taken against the axis, French armed forces had taken the field, and local supplies and services were being furnished. The story was repeated throughout the advance toward Germany, whether through Allied, friendly, nonbelligerent, or other class of area. Before the Normandy and southern France operations were launched, the Italians were at work for the Allies and had divisions in combat and supply services in operation. Before the Siegfried line was penetrated, aid was being received from the metropolitan French, the Belgians, Dutch and Luxembourgers. In the Pacific, the situation was quite different. There, until Manila was reached, the areas occupied by U.S. army and navy forces were sparsely settled by natives devoted to minor agricultural pursuits, and the problems presented by large concentrations of peoples in industrial centres were not present. At most, the civil affairs operations there were no more than small-scale exchanges of goods for services, with minor relief and health operations. In some of these operations the U.S. forces were assisted by Australian and Dutch civil affairs personnel. U.S. forces did not engage in civil affairs in the Balkan countries. Its Balkan operations were limited to small forces for relief and rehabilitation in support of its Allies.

It was never necessary for the army or the navy to assume responsibility for the government of any of the liberated countries occupied. In western Europe, civil affairs agreements were made at the military level with the governments in exile concerned, in advance of occupation where possible. Under these agreements the governments concerned exercised authority and assumed responsibility for the government of their own countries. They pledged support to the Allied forces in their mission against the axis. While there was provision for assumption of complete control by Allied commanders if a government should break down, it was never necessary to exercise this power in any country. Entry on to the Italian mainland had been under an armistice agreement which provided for the return to an acceptable Italian government, the responsibility for the government of territory when occupied and when conditions warranted relaxation of military control. On cessation of hostilities in Europe and the far east in 1945, national governments existed in all liberated territories. Most of these areas which had been occupied and dominated for several years by the axis powers were then lending material aid to the Allied forces.

In the postwar period, the major civil affairs responsibility of the United States was in Germany, Austria, Italy, Japan and Korea. In Italy there were only two provinces under Allied control pending territorial settlements; Korea, controlled in the north by Russia and in the south by the United States, because of the long domination by the Japanese, was without political experience and a trained corps of government personnel to assume responsibility for its government; Austria, although divided into four zones for occupation purposes, was governed by a freely elected Austrian central government subject to control by the Allied high commissioners pending execution of a peace treaty. Germany was without a central government and was controlled by the four-power Allied Control council in Berlin when interallied agreement was possible, or on a national zonal basis when agreement was impossible. Japan was administered as a unit by the United States with the assistance and advice of its allies.

At the end of the year following cessation of hostilities, it was possible to measure factually the extent to which the primary objectives had been attained. Beginning with the liberation of axis-held areas, and the first occupation of axis territory, the Allied forces were confronted with a problem created by the axis' policy of conscripting labour in conquered countries and exploiting the resources of areas occupied by their armies. As a result of this policy, the Allies were faced with the repatriation of approximately 10,000,000 civilians and almost 10,000,000 military personnel. In the fall of 1946 the task of moving this huge mass of people was more than 90% completed. There were 6,000,000 displaced persons repatriated from Germany, of which 2,500,000 were from the U.S. zone. Some 350,000 remained in the U.S. zone, voluntary nonrepatriables who for political, economic and other reasons did not desire to return to their homes and who, under U.S. policy, were not forced to do so. Some 800,000 German civilians were expelled from the Sudetenland, Czechoslovakia and elsewhere in Europe and moved to Germany; 2,000,000 Japanese civilians from Korea, China and elsewhere in the far east; and 1,000,000 Koreans from Japan. The axis had, through varying degrees of coercion, imported millions of enforced labourers and had sent out millions of their own nationals to exploit occupied areas militarily and economically.

The civil affairs subject in occupied axis areas of most immediate interest within the United States was the

purging of nazis and Japanese ultranationalists both from government and positions of influence in commerce and industry. These were the people charged with guilt for the war; the party members, collaborators and other adherents; the jingoists, chauvinists and expansionists. In the U.S. zone of Germany, of 1,456,467 persons in government and business screened by the civil affairs organization, 373,762 were disqualified from holding any government or private position higher than that of labourer. In the summer of 1946, de-nazification in the U.S. zone was so far advanced, and responsible German government for the zone was so well established that further denazification was delegated to the Germans to act under supervision and direction of the military governor. In Japan, where a government was found intact and willing to carry out the orders of the supreme commander, purging of ultranationalists from the outset was made a responsibility of the Japanese acting under direction of the supreme commander. By Oct. 1946, 186,000 Japanese had been dismissed from government positions.

One year after cessation of hostilities, the military forces of the axis had been demobilized and the organization destroyed. Destruction of the economic war potential of the axis nations had progressed, but only to the limit of agreement among the Allies; reparations had progressed to a similar point.

In the same period, much progress was made in the establishment of representative and responsible governments. A free press and democratic educational systems were being encouraged, and substantial results had already been achieved. Freedom of religion had been established throughout the occupied areas. Prior to the final defeat of Japan, except in Korea, liberated nations had re-established governments, freed of the quislings and the puppets. Korea had been under Japanese rule for 35 years. In that period, the Japanese had pursued a policy which prevented training of Koreans in government unless they demonstrated affection for Japanese control and disaffection for an independent Korea. The basic U.S. policy was to sponsor political growth among the Koreans and to train Koreans to administer their own government. There were Koreans in every department of government to whom all possible responsibility was delegated. Political parties had been organized and their leaders were advising the U.S. commander. In the U.S. zone, a legislature was in the process of creation. After liberation of southern Korea, U.S. forces dismissed all of the 70,000 Japanese and disaffected Koreans in government office; all Japanese were dismissed from business and other private employment; and all Japanese were repatriated from southern Korea. In Japan, much progress was made in the democratization of the dictatorial government. Political parties were established; democratic national elections, in which women participated for the first time, were held; and the constitution, rewritten to include democratic principles, was considered in the legislature. A revived press, freed of traditional control, played an important role in informing the public of the issues and in constructive criticism of the draft constitution.

Italy was under control of its own elected government, subject to authority exercised for the security of Allied troops by the Allied commander in one small area. The Austrians had re-established a freely elected government which assumed responsibility for administration of the nation. In Germany, while Allied disagreements had prevented the creation of German central administrative agencies as provided for by the Potsdam declaration, political parties had been organized and were active. In the

U.S. zone, political development had gone much further than it had in the zones of its Allies. Until Sept. 1946, the U.S. zone was the only one where elections had been held and local government administered by freely chosen officials. Early in September, elections were held in the soviet zone. Governments of the three states in the U.S. zone were headed by German minister presidents, appointed by the U.S. commander. These three also sat as a council of three, responsible for the central administration of the U.S. zone.

Defeat of the axis, liberation and re-establishment of free governments in Allied and friendly nations, and control of axis areas required investments by the Allied Nations in civilian supplies. Occupation costs in axis areas were a responsibility of the axis, but repayment had to await production of goods. To Oct. 1946, realization of the major U.S. objectives had required importation by the U.S. army into liberated and occupied areas of 8.522,104 tons of food, clothing and other civilian supplies. Of this amount, 7,834,467 tons went to Europe, and 687,637 tons to the far east. After cessation of hostilities and re-establishment of law and order, the United States began to realize returns on its investments, and goods began to move from the axis areas to the United States.

The United States undertook to apprehend persons who could be identified with specific crimes against U.S. nationals. This program was initiated even before hostilities ceased, and resulted in the arrest of more than 10,000. The trial before military commissions proceeded in a methodical way both in Europe and the far east. As of Aug. 1, 1946, the U.S. forces had arrested 16,000 suspects or material witnesses in war crimes for trial before U.S. military courts; 504 such trials had been conducted by the U.S. army, resulting in 457 convictions and 47 acquittals.

The trial of the 49 major war criminals at Nuernberg and Tokyo by the International Military Tribunals received greater public attention than the many trials of those who committed offenses against U.S. nationals. Those trials were of persons alleged to have committed crimes "against the peace," which meant in effect, planning, preparation, initiation and waging of wars of aggression, and "crimes against humanity" which referred to murders, extermination, enslavement and deportation and other inhuman acts committed against civilian populations as well as violations of the laws of war. (See WAR CRIMES.)

By the end of 1946, civil affairs in axis areas was shifting from negative to positive action. The first year had been spent in ridding, purging and correcting. Before it was possible to undertake positive steps to aid in the development of democratic institutions in the political, economic and social life of these totalitarian nations, it was necessary to restore order and stability to the communities. In 1946, native governments were functioning, schools were reopened and consumer goods were produced. Plans were also being executed to assist the peoples of these nations in developing a democratic way of life by information from abroad and by participation at home. Through newspapers, books, radio and motion pictures these people were being acquainted with the differences between a free and a regimented society. Through elections, drafting of constitutions, revisions of educational systems, labour laws and civil service, these people were beginning to learn the responsibilities and privileges of democracy in action. They were being acquainted with the differences between government for the benefit of the "state" (the political group in power) and government

in which the welfare and interest of the individual citizen was paramount.

Alphonso XIII

King Alphonso XIII of Spain (1886–1941), was born May 17, 1886, in Madrid. In 1939 the Franco government decreed the restoration to Alphonso of property valued at about \$8,500,000, which had been confiscated by the Spanish republic in 1932. Two weeks before his death the former monarch issued a manifesto renouncing his rights to the Spanish throne (which he fled after the "bloodless revolution" of April 1931) in favour of his son, Don Juan, whom a monarchist faction hailed as the future Juan III. Alphonso died in Rome, Feb. 28, 1941. The Franco government granted permission for his burial in the royal pantheon of the Escorial near Madrid.

Aluminum

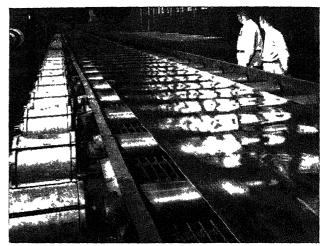

In addition to the major producers listed in Table I, there were minor outputs in Austria, Brazil, China, Hungary, India, Spain, Sweden and Yugoslavia. All except Brazil, China and India were producers in 1937, while the others were added after that year. Plans were underway in 1946 for the construction of a reduction plant in Australia.

This aluminum rolling mill at Alcoa, Tenn., was the largest in the world when it went into operation months ahead of schedule in 1942. The photograph shows one sheet, as long as two city blocks, rolling off a continuous mill

As is indicated in Table I, war demand quadrupled output as compared with that of 1937, and almost tripled it as compared with 1939. The bulk of the increase between 1937 and 1939 was in axis countries, in active preparation for the coming struggle, while subsequent increases measured the Allied response. In this comparison the records of Canada and the United States were particularly outstanding. In both cases, output was expanded six times over that of 1939; the combined output was twothirds of the world total in 1943, against one-third in 1939. Although the output available to the axis countries had about doubled between 1939 and 1943, partly because of increases in their own capacity but more because of their control of occupied and satellite countries, this expansion was not sufficient to offset the enlarged Allied output, and the percentage of the world total under axis control declined slightly.

The salient statistics of the aluminum industry in the United States are shown in Table II.

In spite of a sixfold expansion of U.S. aluminum production during the war years, demand greatly exceeded output, requiring heavy imports, mostly from Canada. Recoveries of secondary metal were also greatly enlarged, but most of

this increase was in the reworking of new plant scrap, and only a relatively small amount of old scrap was brought back from the pool of metal in use. In this connection it may be noted that large amounts of scrap became available from the thousands of aeroplanes left over from the war; the handling of this surplus presented a major problem.

An important feature of the postwar disposal of U.S. government-owned plant capacity was the effort to strengthen the competitive position in the domestic aluminum industry. This action was in

From

accordance with the court decision of March 1945 which found that the Aluminum Company of America was a monopoly in some phases of its operations. To offset this situation it was provided that in the disposal of surplus government facilities, no sales would be made to Alcoa that would strengthen their monopolistic control; plants in this category could be sold only to competitors of Alcoa. Accordingly, sales or leases on a number of government plants were arranged with two competing companies.

Ambassadors

The following is a list of ambassadors to and from the United States and to and from Great Britain from 1938 through Jan. 1, 1947.

		•				
To and From the United States						
	To	From				
Argentina .	Espil, Felipe A. (1938-43, absent 1944)	Weddell, Alexander W. (1938-39) Armour, Norman (1940-44) Braden, Spruille (April-Aug.				
	Escobar, Dr. Adrian C. (1945)	1945)				
	Ibarra, García Dr. Oscar (absent, 1946)	Messersmith, George (April 1946–47)				
Belgium	Ivanissevich, Don Oscar (1947) Straten-Ponthoz, Count Robert van der (1938–44) Silvercruys, Baron Robert (1945–47)	Gibson, Hugh S. (1938) Davies, Joseph E. (1939–40) Biddle, Anthony J. D., Jr. (1942–44)¹				
Bolivia	Guachalla, Dr. Luis F. (1943–44) ³ Andrade, Victor (1945–46) Martinez Vargas, Don Ricardo	Sawyer, Charles (1945) ² Kirk, Alan G. (1947) ² Boal, Pierre de L. (1943–44) Thurston, Walter (1945–46) Flack, Joseph (1947)				
Brazil	Aranha, Oswaldo (1938)	Caffery, Jefferson (1938-44) Berle, Adolph A., Jr. (1945-46) Pawley, William D. (1947)				
Canada	Brandão, Mario de P. (1939) Martins, Carlos (1940-47) McCarthy, Leighton (1944) ³ Pearson, Lester B. (1945-46) Wrong, Hume (1947)	Pawléy, William D. (1947) Atherton, Ray (1944–47)				
Chile	Trucco, Manuel (1938-39) Cabero, Alberto (1940-41) Michels, Rodolfo (1942-44) Mora, Marcial (1945-46) Nietro del Rio, Don Felix	Armour, Norman (1939) Bowers, Claude G. (1940-47)				
China	Wang, Chengting T. (1938) Hu Shih, Dr. (1939–42) Wei Tao-ming, Dr. (1943–46) Koo, Dr. V. K. Wellington (1947)	Johnson, Nelson T. (1938-41) Gauss, Clarence E. (1942-44) Hurley, Maj. Gen. Patrick J. (1945) Marshall, Gen. George C.				
Colombia	Pumarejo, Miguel L. (1939)* Turbay, Dr. Gabriel (1940–42) Vargas Nariño, Alberto (1943) Turbay, Dr. Gabriel (1944–45) Sanz de Santamaria. Carlos	(1946) Stuart, J. Leighton (1947) Braden, Spruille (1939–41, absent 1942) Lane, Arthur Bliss (1943–44) Wiley, John C. (1945–47)				
Costa Rica.	(1947) Escalante, Carlos M. (1944) ³ Gutierrez, Francisco de P. (1945–47)	Des Portes, Fay A. (1944) Johnson, Hallett (1945-47)				
Cuba	Martínez Fraga, Dr. Pedro (1938-41) Concheso, Dr. Aurelio F. (1942-44)	Wright, J. Butler (1938-39) Messersmith, George S. (1940-41)				
	(1942–44) Belt, Guillermo (1945–47)	Braden, Spruille (appointed, 1942) (1943–45) Norweb, R. Henry (1947) Biddle, Anthony J. D., Jr.				
Czechoslo- vakia	Hurban, Vladimír (1944–46) ³ Slavik, Dr. Juraj (May 1946)					
Dominican Republic .	Copello, Anselmo (1944) ³ García Godoy, Emilio (1945-46)	Steinhardt, Laurence A. (1945-47) Warren, Avra M. (1944) Briggs, Ellis O. (1945) McGurk, Joseph F. (1946) Butler, George H. (1947) *Long, Boaz W. (1939-43)				
Ecuador	Alfaro, Capt. Colón E. (1939–44) ³ Plaza, Galo (1945–47) Yllescas, Dr. Don Francisco (1947)	Scotten, Robert M. (1944–46)				
Egypt El Salvador.	Hassan Bey, Mahoud ³ (1947) Castro, Dr. Hector D. (1944) ³ *Castlo, Roberto (1945)	Tuck, S. Pinkney (1947) Thurston, Walter (1944) Simmons, John F. (1945–47)				
France	Saint-Quentin, Count de	Bullitt, William C. (1938–40) Leahy, William D. (1941–42) Caffery, Jefferson (1945–47)				
Germany	Henry-Haye, Gaston (1941-42) Bonnet, Henri (1945-47) Dieckhoff, Hans H. (1938-39, absent 1940-41)	Dodd, William E. (1938) Wilson, Hugh R. (1938–39)				

Great Britain	Lindsay, Sir Ronald (1938–39) Lothian, Marquess of (1940) Halifax, Viscount (appointed 1940) (1942–46) Kerr, Sir Archibald Clark (1946) Inverchapel, The Rt. Hon. the Lord (1947)	Bingham, R. W. (1938) Kennedy, Joseph P. (1938–41) Winant, John G. (1942–46) Harriman, W. Averill (1946) Gardner, O. Max (1947) (Died_before taking post)
Greece Guatemala .	Lord (1947) Diamantopoulos, Cimon P. (1943–46) ³ Economou-Gouras, Paul (1947) Recinos, Dr. Adrian (1944) ³ Silva Pena, Eugenio (1945)	Biddle, Anthony J. D., Jr. (1943) MacVeagh, Lincoln (1944–47) ⁵ Long, Boaz (1944–45) Kyle, Edwin Jackson (1946)
Haiti	Garcia Granados, Jorge (1947) Liautaud, André (1944-45) ³ Antoine, Jacques C. (1946) Charles, Joseph D. (1947)	White, John C. (1944) Wilson, Orme (1945–46) Tittmann, Harold H., Jr.
Honduras	Cáceres, Dr. Julián R. (1944–47) ³	(1947) Erwin, John D. (1944–47)
Iran	*Shayesteh, Mohammed (1945) ³ Ala, Hussein (1947)	Morris, Leland B. (1945) Murray, Wallace (1946) Allen, George V. (1947) Phillips, William (1938-41) Kirk, Alexander C. (1945-47)
Italy	Suvich, Fulvio de (1938-39) Colonna, Ascanio d.p. (1940-41)	Phillips, William (1938-41) Kirk, Alexander C. (1945-47) Dunn, James Clement
Japan	Tarchiani, Alberto (1947) Saito, Hirosi (1938) Horinouchi, Kensuke (1939–40) ⁶ Nomura, Kichisaburo	Grew, Joseph C. (1938-41)
Luxembourg	(appointed, 1941) *Le Gallais, Hugues (1945-47)3	Sawyer, Charles (1945)2
Mexico	Castillo, Nájera, Dr. Francisco (1938–45)	Daniela Josephys (1938–41)
	Espinosa de los Monteros, Dr.	Messersmith, George S. (appointed, 1942) (1943–46)
Netherlands.	Antonio (1946) Loudon, Dr. A. (1943–47) ³	Messersmith, George S. (appointed, 1942) (1943–46) Thurston, Walter (1947) Biddle, Anthony J. D., Jr. (1943–44)
Nicaragua .	Sevilla Sacasa, Guillermo (1944–47)³	Hornbeck, Stanley K. (1945-47) Stewart, James B. (1944-45) Warren, Fletcher (1947) Biddle Anthony I. D. Jr.
Norway	Munthe de Morganstierne, Wilhelm (1943–47) ³	(1943–44)
Panamá	Boyd, Dr. Augusto S.	Osborne, Lithgow (1945–46) Bay, Charles U. (1947) Dawson, William (1940–41)
	(absent, 1940) ⁸ *Ehrman, I. H. (1941)	Wilson, Edwin C. (1942–43) Warren, Avra (1945)
	Boyd, Dr. Augusto S. (absent, 1940) ³ *Ehrman, J. H. (1941) Jaén, Guardia, Ernesto (1942–43)	Bay, Charles U. (1947) Dawson, William (1940–41) Wilson, Edwin C. (1942–43) Warren, Avra (1945) Hines, Brig. Gen. Frank T. (1947)
Paraguay	Jiménez, E. A. (1944-45) Vallarino, Dr. J. J. (1947) Valázquez, Dr. Celso R. (1943-46) ³	Frost, Wesley (1943-44)
Peru	*Acasta, Dr. Don Cesar K.	Beaulac, Willard L. (1945-47) Steinbardt Laurence A

American Citizens Abroad

After the close of World War I, U.S. citizens in everincreasing numbers journeyed abroad for business, pleasure, health cures, study and other varied reasons. The peak of this travel was reached in 1937, when 168,016 new passports were issued and the census showing the number of U.S. citizens already abroad totalled 390,437. For many years the value of U.S. citizens living abroad as well as the value of those travelling temporarily for business or pleassure had been recognized as a potent factor in international trade as truly as it was a factor in the maintenance of good will and understanding and in the pursuit of cultural activities. The dollars spent by U.S. citizens temporarily travelling abroad in the year 1937 was estimated to have been \$472,000,000, which constituted in the eyes of those studying commerce among the nations of the world a most important U.S. import. This sum of money represented the expenditures of 500,000 U.S. citizens for their maintenance, their pleasure and their travel. In 1939, with travel restricted by the passage of the Neutrality act to areas which could be reached without passing through

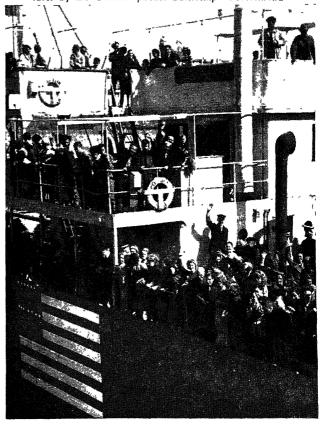

what were officially proclaimed as combat areas, the number of U.S. citizens abroad was materially decreased, both with respect to those in residence and with respect to the temporary travellers. The issue of U.S. passports had already dropped off by about 34,000 in 1938 as war seemed to draw nearer, and the census figures of those living abroad showed a comparable decrease for the year. A steady decline in the number of U.S. citizens travelling abroad and those maintaining residence outside the home country was apparent throughout the years 1939, 1940 and 1941. In an attempt to withdraw U.S. citizens from the highly troubled areas of the world, ever-increasing limitations and restrictions on travel were promulgated by the authorities in Washington, D.C. As the war clouds finally broke and the storm of World War II increased in scope and fury, those persons unnecessarily remaining outside their native land were urged to leave the troubled areas while there was time. The efforts of U.S. authorities were directed toward evacuation from Europe and the far east of those who could be persuaded to leave. At the same time, as the danger of the submarine warfare increased, only such travel from the United States as was considered imperative was permitted. It was considered imperative, according to the traditions of the United States, to permit the travel, even through combat seas, of nurses, ambulance drivers, relief workers and others on errands of mercy and assistance. Business and family travel was judged by the same standards of necessity and help. The shortage of return transportation to the United States was overcome for a time by government chartering of certain merchant ships to care for its stranded citizens. Publication of the opportunities to proceed homeward was general throughout the world, and U.S. diplomatic and consular officers urged citizens not to delay their departure and endanger their safety even though it involved sacrifice of material things. Nevertheless, when in Dec. 1941 the tragedy of Pearl Harbor plunged the United States into the war, thousands of U.S. citizens were caught in the areas of actual combat. With every ton of shipping put in use for war-essential travel, many of these people still remained outside the United States, awaiting transportation homeward. The known and registered U.S. citizens were speedily joined by others with technical claims to citizenship which would never have been asserted had not safety of life demanded the exertion of every effort toward escape from the lands overrun by the conqueror. With the departure from axis territory of U.S. diplomatic and consular officers, the chance of departure of private citizens disappeared. The welfare and protection of U.S. citizens still within the axis' power was entrusted to the Swiss diplomatic and consular representatives. It was estimated that toward the close of the year 1946, some 59,940 still awaited repatriation, some being fully documented and others awaiting their turn for processing to start the homeward journey. The rough estimates on this subject showed the following approximations:

Albania	200	Germany	7,000
Austria	1,000	Hungary	36o
Bulgaria	50	Italy	12,000
Czechoslovakia	800	Japan	5,000
British Isles	500	Poland	20,000
Finland	്ദര	Rumania	450
France	50	U.S.S.R.	2,000
Greece	7,000	Yugoslavia	3,500
	-	-	50.040

Simultaneously with the program looking to the return of U.S. citizens abroad, the presidential proclamation of Nov. 14, 1941, was issued requiring every citizen of the

United States, including seamen who should enter or depart from the United States, to possess a valid passport. The presidential proclamation was followed by the regulations of the secretary of state dated Nov. 26, 1941, which provided exemptions for members of the armed forces, the Red Cross and civilian employees of the war and navy departments. All other U.S. citizens were obliged to carry valid passports and their entry into and departure from the United States was checked by officers of the government services especially instructed for this work. This control enabled the government to expedite travel of those on war work all over the world, conserving transportation for urgent requirements arising constantly in remote or nearby areas. Arrangements were made with foreign countries through whose territory uniformed men were obliged to pass to expedite this transit on purely military documentation, omitting passports and customary visas. Neutral countries such as Portugal and Eire could not facilitate travel of uniformed men but expedited other official travel in all possible ways. Thus, the normal peacetime work of promoting the travel of U.S. citizens to destinations abroad and engaging in negotiations looking to relaxation of onerous travel requirements became a security work of preventing anything in the way of travel not essential to the prosecution of the war and at the same time expediting the travel of the hundreds of thousands of civilians employed to carry on essential war work, from the building of quonset huts to the completion of harbour works, the building and maintenance of air bases, the transportation of all lend-lease and war supplies carried by the merchant marine. The territory covered in these activities ranged

American and Canadian survivors of the torpedoed "Athenia" arrived Sept. 13, 1939, at Halifax aboard the U.S. freighter "City of Flint," which was captured as a contraband carrier a month later by the German pocket battleship "Deutschland"

Scene aboard the U.S. liner "Manhattan" Sept. 7, 1939—as returning U.S. citizens hastened to leave war zones

from Iceland to Ascension Island in the Atlantic, Africa, the middle east, China, the Pacific islands, Australia and New Zealand, as well as into most of the countries of the Americas. U.S. civilians on duty service travelled constantly and extensively all during the hazardous days of the war. U.S. merchant seamen delivered their cargoes despite the fury of submarine and air warfare, neither hardship nor casualties interfering with the progress of the work. The issue of passports during the war years was predicated not only upon customary proof of U.S. citizenship and travel essential to the war effort, but upon the satisfactory security check carried out by the agencies of the government authorized to do such work.

During 1939 and 1940, the Flying Tigers, American Field service, American hospital in Britain, American Legion Ambulance corps, American Volunteer Ambulance corps and many other organizations lent their aid in addition to the American Red Cross, the Friends Service committee and others long engaged in humanitarian work.

On April 10, 1941, the well-known red U.S. passport was replaced throughout the world by a new passport completely different in colour and content. The bearers of red passports were required, if living abroad, to appear personally before the nearest U.S. consul and, after being fingerprinted and otherwise properly identified, were issued the new passports for the unexpired validity of the old one. In this way the government was able to make useless hundreds of U.S. passports which had been acquired by certain foreign governments for illegal use by agents and spies, and at the same time have an opportunity to make personal contact with bona fide U.S. citizens and document them with more security. Those persons who returned to the United States after Sept. 1939 had their passports lifted at the port of entry and deposited with the government for replacement by the new type passport provided the bearer was authorized again to proceed abroad.

The breakdown of all normal financial transactions made life exceedingly difficult for U.S. citizens abroad after the United States entered the war, and the government endeavoured through the good offices of the Swiss representatives to make available to destitute citizens an allow-

ance sufficient to feed and care for them, along the very simple standards possible in most places. As the war progressed, however, most U.S. citizens were confined in concentration camps, only to be liberated in a rather small number of cases through exchange of civilians, or in the great majority of cases by the successful progress of the Allied troops. There were many U.S. citizens of dual nationality known only to the authorities by their foreign nationality. These in large numbers concealed their U.S. citizenship and were able to assist the Allies through their co-operation or to aid the axis, according to the strength of loyalty to the United States of the individual citizen. Some few were charged with treason; more were charged with collaboration with the axis, but most were loyal and rode out the axis control as best they could.

On Nov. 20, 1943, the president directed the joint chiefs of staff, in consultation with the department of state, to specify areas of active military operations into or through which civilians, other than those under the control of the joint chiefs of staff, agents of the department of state or persons whose travel was authorized by the president, might not go without specific approval of the joint chiefs of staff. This specific approval was directed to be sought by the chief of the passport division, acting for the secretary of state, in connection with the issue of passports. This same official was authorized to act for the secretary of state in consultation with the joint chiefs of staff in determining the areas to be designated primary military areas. In Nov. 1943, when the primary military areas were first established, all Allied and occupied countries were included in this restricted area. There was a gradual freeing of areas until at the end of 1946, only Austria, Germany, Korea and the main islands of Japan, Nansei Shoto and Nanpo Shoto remained as primary military areas.

At the close of 1946, U.S. citizens again could travel freely in the western hemisphere without U.S. passports unless the foreign country required the traveller to present one. Areas not requiring either passports or visas from U.S. citizens temporarily visiting them included the Bahamas, Bermuda, Canada, Canal Zone, Costa Rica, Cuba, Dominican Republic, El Salvador, Guatemala, Honduras, Jamaica, Mexico, Newfoundland, Panamá and Venezuela. These countries required in most cases that the visit be not more than 30 days, some granting 60 days and others up to 6 months.

For the rest of the world, travellers were requested to confine trips to those countries where their presence was required by compelling reasons. U.S. citizens travelling unnecessarily to areas of the world struggling to recover from the effects of the war were kept to a minimum in order not to add to the extremely critical food and housing conditions prevailing. Travel to Bulgaria, Rumania and Hungary continued greatly restricted by the Allied Control commission, and the granting of permission to enter those countries was still limited to persons conducting business of national importance. Requests for permission of the Allied Control commission to enter Bulgaria, Rumania and Hungary had to be made through the passport division, department of state. Travel to certain areas of China continued difficult and restricted, and U.S. citizens were cautioned to communicate with the nearest U.S. consular officer upon arrival in China before proceeding to the interior of that country or to north China.

The decade 1937–46 closed with the strongly expressed hope from most of the countries of Europe that transportation, food and housing conditions would soon be sufficient to warrant the resumption of the much-needed U.S. plcasure travel.

Statistics concerning U.S. citizens residing abroad as of Jan. 1, 1946, follow in so far as they were available at the end of the decade.

American Literature

Although many intelligent critics and reviewers viewed the approximately 100,000 titles of the decade 1937-46 with more dismay than pleasure, there were enough good books among this multitude to justify a belief that American literature was continuing to mature. At least 1,000 of the 100,000 deserved readers for years to come; perhaps 100 of them would live longer than the 20th century.

Not many of the books that deserved a more or less prolonged life were big best sellers, however. At the beginning of the decade, Margaret Mitchell's competent romanticization of southern history, Gone With the Wind (1936) and Dale Carnegie's blue book to success, How to Win Friends and Influence People (1938) were shattering all sales records. At the decade's close, Betty MacDonald's The Egg and I (1945), a lightly told story of life on a wilderness chicken ranch, and Taylor Caldwell's This Side of Innocence (1946), another period piece, outsold many more expert works in fiction and nonfiction. In the years between, cleverly concocted mixtures of unexacting religiosity, rosily viewed history, and near-pornography usually led the best seller lists. The cynical claimed that even such serious books as Native Son (1940), For Whom the Bell Tolls (1940) and The Grapes of Wrath (1939), all of which were both popular and critical successes, sold well because of their frank treatment of sex rather than because of the penetrating interpretation of life they presented.

It was undoubtedly true that most serious older and

younger writers found sufficient readers to earn them publication, if not a luxurious livelihood. Despite the emergence of publishing as a big business and an increasing tendency to retail books with as assured a popular appeal as a name-brand soap, the decade was rich in excellent books. Such writers as Hemingway in fiction, the Beards in history, Frost in poetry, Matthew Josephson in biography and Van Wyck Brooks in criticism wrote and published with little or no diminution in their previously established reputations for quality. Exciting and excellent new talents such as the poet Karl Shapiro, Arthur M. Schlesinger Jr., the historian, and the critic John Crowe Ransom continued to emerge and get the praise of both readers and critics.

The general level of competence was high indeed. Most authors wrote in a vivid, colloquial style that was unpretentious but accurate. Most books moved rapidly without too great a sacrifice of whatever depth the authors were able to penetrate. This was true of even the mystery stories that began to circulate more widely than ever before in the various pocket book series that started during the decade, and of the many I-was-there books by reporters that flooded the war and postwar book market.

Dashiell Hammett, Raymond Chandler, Craig Rice and others wrote almost as well, though not as meaningfully, as Hemingway, while John Hersey, Vincent Sheean and a number of other reporters seemed to have mastered the art of writing rapidly and perceptively at the same time.

The Novel

But most of the decade's best-selling novelists preferred to ignore the deepening shadow of war. There was war and trouble in a good many of the novels with big sales, but it was war and trouble safely embalmed in the past. Margaret Mitchell's Gone With the Wind (1936), Laura Krey's And Tell of Time (1938) and a host of slightly less popular novels such as Elizabeth Pickett Chevallier's Drivin' Woman (1942) continued to quarry the seemingly inexhaustible vein of Civil War and reconstruction days material. The American Revolution was almost as popular. In addition to many lesser novels, there was Kenneth Roberts' Oliver Wiswell (1940), a competent fictionalization of the revolution from a Tory point of view, and Howard Fast's Citizen Tom Paine (1943), one of the best accounts that had yet appeared of the difficult time American "liberal" leaders had in unifying the common man and beating the British.

Roberts and Fast were the only best-selling novelists of the decade who repeated their popular successes. Roberts' exciting account of Major Robert Rogers and the Northwest Passage (1937) had reached as many readers as Oliver Wiswell. Both of his novels were unusually authentic in detail and unusually faithful to historical documents, although liberal critics questioned his unsympathetic treatment of such American notables as Samuel Adams and Benjamin Franklin. It was with the conservative critics. on the other hand, that Fast had his trouble, for most of them disapproved what they regarded as his left-wing interpretation of the American past. His first novel, The Last Frontier (1941), a sympathetic portrayal of the Indian underdog, sold too few copies for the good novel it was, but his later books were big sellers. The Unvanquished (1942), called the best novel about Washington, and Citizen Tom Paine were outstanding among modern historical novels for their speed of movement and their thorough absorption of the detail of the past. His Freedom Road (1944), a moving portrayal of the difficulties of the intelligent Negro in the 19th century, and The American (1946), a novel about the troubled life of Gov. John Peter Altgeld of Illinois, were almost as good fiction though less reliable history. The work of both Roberts and Fast proved that historical fiction could do without the romantic distortion and the overemphasis of sex that had almost become the trade-mark of the genre.

Though the novels of Fast, Roberts and a few others pleased the critical who thought that literature should illuminate life, most best-selling fiction did not. The great majority of best sellers evaded rather than presented the grimmer realities. In this respect, both Kathleen Winsor's Forever Amber (1944) and Lloyd Douglas's The Robe (1942) were at one, since both of them managed to invest their respective historical periods with an aura for which sober historians could see little excuse. Much the same comment was deserved by Betty Smith's A Tree Grows in Brooklyn (1943), which, though it started out as authentically as a Farrell novel, faded into an Alger girl story in the last 200 pages about its slum-born heroine. More authentic and more illuminating, yet all this side of profound, were Christopher Morley's story of a working girl, Kitty Foyle (1939); Marjorie Kinnan Rawlings' tale of the life of a boy in the Florida back-country, The Yearling (1938); J. P. Marquand's account of the troubled life of a New Englander caught between the values of the old New England and the new New York world, H. M. Pulham, Esq. (1941); and Lillian Smith's fictional analysis of the racial tensions that led to a lynching in a small southern town, Strange Fruit (1944). All of these novels were well above average in competence, honesty and insight, but none of them penetrated the problems they presented with sufficient profundity to make one feel they would long outlast the decade in which they were printed.

Decline and Rise of Dreiser's Generation.—Of the novelists who established reputations before or during World War I, only three-James Branch Cabell, Booth Tarkington and Upton Sinclair-continued to publish in any quantity. A novel, The Buccaneers (1938), and a volume of short stories, Ghosts (1937), were published after Edith Wharton's death in 1937, but neither of them seemed equal to The House of Mirth (1906) or The Age of Innocence (1920). Theodore Dreiser's first novel in 20 years, the posthumously published The Bulwark (1946), made most discerning readers regret the long silence that preceded his death in 1945. It was shorter and better integrated than the books that made his reputation, and yet nearly as powerful as An American Tragedy (1925). Specifically, The Bulwark dealt with the conflict between two generations in a Quaker family, but it could almost stand as a fable of the plight of the religious man in a civilization increasingly dedicated to material values. Dreiser's near contemporary, Sherwood Anderson, who died in 1941, published no novels during the decade, but his Memoirs (1942) was likely to outlast all of his novels and all but a few of his short stories. It was one of the most honest and humble of autobiographies and deserved to rank with The Autobiography of Lincoln Steffens (1931) and The Education of Henry Adams (1907).

Two other writers of Dreiser's generation published sparingly but well. Willa Cather's Sapphira and the Slave Girl (1940), a delicate account of sexual rivalry between a slave and her mistress in pre-Civil War days, was not as ambitious in substance as her earlier novels, but it was as skilfully done as all but her best books. Ellen Glasgow, who had never been especially popular with either the

public or the critics, won both praise and readers with In This Our Life (1941), the Pulitzer prize winner for the year, while her book about her writing, A Certain Measure (1943), earned her a higher reputation among serious critics than she had ever had before. In This Our Life, the last novel she completed before her death in 1945, was an illuminating fictional exploration of the complex conflicts between two generations in a declining southern family, but it went beyond these specific conflicts to a dramatic analysis of many fundamental moral, social and economic problems of the time.

The three novelists in this older group who wrote the most neither received nor deserved much critical acclaim. Booth Tarkington continued to publish such novels as Rumbin Galleries (1937) and The Heritage of Hatcher Ide (1940), but he wrote nothing that approached the quality of his serious Alice Adams (1921) or his delightfully light Peniod (1914) and Seventeen (1917) before his death in 1946. In similar fashion, James Branch Cabell, although he continued to write deft novels such as Smire (1937) and First Gentleman of America (1942), failed to equal the witty sophistication of The Cream of the Jest (1917) and Jurgen (1919). Never as popular with the critics as either Cabell or Tarkington, Upton Sinclair continued his dauntless way with a book or two each year of the decade. The most notable of these were the Lanny Budd series, extending from World's End (1940) to A World to Win (1946). These novels could be praised justly for their liberal and exhaustive interpretation of contemporary history, but they were full of stilted incident and pasteboard characters. Nevertheless, most critics were happy to see Sinclair win the Pulitzer prize in 1942 with one of the Lanny Budd series, Dragon's Teeth. They felt it was a deserved tribute to the integrity of a man who had selflessly allied himself with almost every unpopular and "good" cause of the

Post-World War I Novelists.-Of the novelists who achieved distinction with books published shortly after World War I, Ernest Hemingway and William Faulkner increased their reputations, while John Dos Passos, who was once regarded as their peer, declined in critical esteem with the printing of Adventures of a Young Man (1939) and Number One (1943). Part of this decline may have been the consequence of Dos Passos's increasing tendency to desert the novel for reportage. Although his Journey Between Wars (1938), a collection of his best travel pieces from the preceding 20 years, State of the Nation (1944), an account of what people were doing, thinking and feeling in wartime America, and Tour of Duty (1946), a report on Europe after the war, were vividly done, they naturally took him away from the novel. So did his excellent study of the basic democratic ideas and their originators, The Ground We Stand On (1941). At any rate, Dos Passos' novels were generally regarded as inferior to the trilogy, US.A., which was published as a whole in 1938. Adventures of a Young Man, though vivid as a picture of American radicalism, seemed hurried and one-sided in its portrait of loyalist Spain. Number One was more satisfactory as a whole, an illuminating portrayal of a Huey Long-like politician, but it too was inferior to Dos Passos's best work in fiction.

Although he published only three books during the decade, Ernest Hemingway emerged from the period with an almost universal reputation as North America's leading novelist. Nevertheless, most critics felt that *To Have and Have Not* (1937), a too rapidly moving and too poorly integrated account of the misfortunes of Harry Morgan, was Hemingway's poorest novel. When For Whom the Bell

Tolls appeared in 1940, it became evident, however, that To Have and Have Not, with its imperfect statement of the author's growing concern for society as a whole, had been a necessary step in the writer's growth. The more discerning, indeed, had already recognized this when they read his play about the Spanish civil war, The Fifth Column, and his magnificent short story, "The Snows of Kilimanjaro" in The Fifth Column and the First Forty-Nine Stories (1938).

For Whom the Bell Tolls, Hemingway's novel of the Spanish civil war, was unquestionably one of the great novels of modern times. Unless it was Leo Tolstoy's War and Peace, there was no novel that compressed with similar eloquence the complex totality of individual sensations, emotions and ideas that modern war brings to consciousness. Hemingway's novel, with its theme that whatever happens anywhere affects everybody everywhere else, was substantiated by the history of the decade. Robert Jordan—confused, yet taking a stand amid the perplexities of a right side not totally right and a wrong side not totally wrong—stood as a symbol of the sensitive man in any war. No other American writer had produced a novel that so securely stood comparison with the better European novels of the period.

Always a voluminous, uneven and brilliant writer, William Faulkner gradually gained a reputation as one of the foremost American writers of fiction. His exploration of the social and emotional history of the south as embodied in the mythical chronicle of Yoknapatawhpha county included three of the better novels-The Unvanquished (1938), The Wild Palms (1939) and The Hamlet (1940)and one of the better collections of short stories (Go Down Moses and Other Stories, 1942) of the decade. His canonization as one of the better writers of the time was completed with the publication of *The Portable Faulkner*, brilliantly edited and introduced by Malcolm Cowley in 1946. Here was a connected story of Yoknapatawhpha county's development from 1820 on that was certainly a parable of southern man, and to some extent a parable of man as a whole, everywhere.

Most of the other novelists of Hemingway's generation published sparingly. Elizabeth Madox Roberts, whose Time of Man (1926) was one of the best books ever written by an American about poverty, turned increasingly to the exploration of the sensitive and thwarted consciousness in Black Is My True Love's Hair (1938) and Not by Strange Gods (1941). Her posthumously published Song in the Meadow (1940) contained some compressed and impressive poems that revealed a good deal about both herself and her native Kentucky. Even more sparing in his publications was Glenway Wescott, whose excellent short novel, The Pilgrim Hawk (1940), a subtle and profound exploration of jealousy, found fewer readers than his vivid but intemperate Apartment in Athens (1945), which fitted the emotional temper of most war-torn readers with its violent fictional attack on the German character. Both Wescott and F. Scott Fitzgerald, who died in 1940 and left the incomplete The Last Tycoon (1941) and the stories, essays and notebooks that were gathered together in The Crack-Up (1945) behind him, rose in critical estimation. Fitzgerald's unfinished novel promised to become one of the few intelligent and comprehending novels written about the film industry, while short pieces such as "The Crack-Up" and the notebooks showed that Fitzgerald might have written even better than he did in The Great Gatsby (1925) if he had lived longer.

Above, left to right: Authors of U.S. best sellers in nonfiction during 1937-46: Oscar Levant (A Smattering of Ignorance), Ernie Pyle (Here is Your War; Brave Men), Margaret Halsey (With Malice Toward Some), Wendell Willkie (One World), Richard Wright (Black Boy)

Three more prolific writers did not fare as well with the critics as their more frugal contemporaries. Despite the fact that it was a penetrating treatment of a woman's search for a social and individual faith, Waldo Frank's The Bridegroom Cometh (1938) was usually regarded as inferior to his City Block (1922) and The Death and Birth of David Markand (1936). His other novels, such as Summer Never Ends (1941), were largely ignored by the critics, although he was deservedly praised for the criticism he made of the American spirit in A Chart for Rough Water (1940), his frequently profound collected essays, In the American Jungle (1937), and his excellent report on Latin America, South American Journey (1943). Sinclair Lewis published more and fared even worse. It was the nearly unanimous opinion of the more discerning reviewers that Lewis's ill-tempered castigation of radical children in his Prodigal Parents (1938), his over-burlesqued portrait of a publicist in Gideon Planish (1943) and his study of divorce in Cass Timberlane (1945) were inferior to the fine social satire of Main Street (1920) and Babbitt (1922), while his light novel of a stage-crazy girl, Bethel Merriday (1940), was ignored by the critics but bought widely by the public. In such novels as The Rains Came (1938) and Mrs. Parkington (1943), slick and shallow treatments of subjects that were certain to attract readers if not critical praise, Louis Bromfield, whose The Green Bay Tree (1924) had promised well, descended into the growing group of novelists whose sensitivity to public reaction enabled them to sell well and to be forgotten rapidly.

Of the other novelists who made reputations in the early 1920s, Ruth Suckow and Thornton Wilder wrote no novels (though Wilder had two highly successful and competent plays, Our Town [1938] and The Skin of Our Teeth [1942] to his credit); Robert Nathan continued to publish slight but effective novels such as Winter in April (1937); Evelyn Scott repeated her turgid but honest attacks on conventionality in such books as Bread and a Sword (1937); and James Gould Cozzens scored a critical and popular success in his exploration of what goes on in the minds of judges and lawyers, The Just and the Unjust (1942).

Depression Novelists.—Most of the novelists who had made reputations in the early years of the depression continued to explore the social irony of poverty in a land of plenty until war absorbed their attention. Of these writers, John Steinbeck was easily the one who most nearly combined popular appeal with unpopular seriousness. His first best-selling novel, Of Mice and Men (1937), a compressed and compassionate story of homeless men, was fol-

lowed by the still more widely sold The Grapes of Wrath (1939), which was acclaimed by many critics as an Uncle Tom's Cabin of the impoverished. Both of these novels deserved to rank with such excellent proletarian novels of the early 1930s as Jack Conroy's The Disinherited (1933) and Robert Cantwell's The Land of Plenty (1934).

Steinbeck's later novels continued to sell well, but they were generally considered inferior by critics. The Moon Is Down (1942) was as economically told as Of Mice and Men and the very good short stories in The Long Valley (1938), but its sentimental portrayal of both the conquerors and the conquered in an invaded Norwegian town made it seem "untrue" as a dramatic analysis of war. Cannery Row (1944), a goodhearted fiction about bums and prostitutes in Monterey, Calif., had neither the compression nor the authenticity of the similar Tortilla Flat (1935). Perhaps the best books Steinbeck did during the war were his collaboration with Herbert Kline, The Forgotten Village (1941), about a small Mexican town, and his collaboration with Edward R. Ricketts, Sea of Cortez (1941), a study in biology that revealed a good deal about both the marine specimens and the philosophy of the novelist.

Erskine Caldwell followed a pattern similar to Steinbeck's. Before World War II broke out, Caldwell had written Trouble in July (1940), one of the best lynching novels to come from the south, and collected his always deit, sometimes moving, short stories about the socially and economically underprivileged into Jackpot (1940). During the war years he spread his genuine talent too thinly through too many books. His novel about the soviet invasion, All Night Long (1942), and his tale of a decadent southern family, A House in the Uplands (1946), were inferior to his earlier novels, while his later books of reportage did not have the force of You Have Seen Their Faces (1937), a photographs-with-text-report on the deep south he did in collaboration with Margaret Bourke-White.

The most steadily producing social novelist of the decade was James T. Farrell, who had made his reputation with Studs Lonigan (1937). An uneven but gifted writer, Farrell's principal work was the completion of a series of books about Danny O'Neill, who came from the same background as Lonigan but made more of a success of his life. In all of these novels (A World I Never Made, 1936; No Star Is Lost, 1938; Father and Son, 1940; My Days of Anger 1943), there was occasional eloquence and a constantly impressive piling-up of detail about his characters and their background. In Bernard Clare (1946), Farrell appeared to be starting another series of novels with his version of the artist as a young man in North America. Many critics wished that he would write less and less cumbersomely and believed he was at his best in such critical studies as The League of Frightened Philistines (1945) and The Fate of Writing in America (1946).

Two other writers of integrity and talent who published too much to sustain the reputations they earned in the early 1930s were Pearl Buck and Vardis Fisher. Fisher's fiction included the typically titled, Forgive Us Our Virtues (1938), his popular novel about the Mormons, Children of God (1939), and a series of three novels about precivilized men and women. The third, Intimations of Eve (1946), was more highly praised than any of its predecessors; this group of books, called The Testament of Man, gave some promise of becoming as important as the earlier tetrology, In Tragic Life (1932), which had the defects of prolixity and the virtues of deep honesty that had always characterized Fisher's writing.

Although Pearl Buck—because of her excellent portrait of a Chinese family, The Good Earth (1931)—probably deserved the Nobel prize for literature as much as any recipient of the honour, her later novels, particularly Other Gods (1940) and Pavilion of Women (1946), did not maintain the quality of her earlier and better work. The Patriot (1939) and Dragon Seed (1942), both books about China at war, were nevertheless fine novels. As she revealed in her nonfiction books, Of Men and Women (1941) and American Unity and Asia (1942) she remained an artful propagandist for a world in which all men could be brothers. No amount of hurried artistry could totally obscure the fundamentally important moral message that impelled all her books.

Frederic Prokosch, like Pearl Buck, was concerned with the total international picture rather than with any specifically American subject. A novelist with an unusual knowledge of many countries and many people, Prokosch gave perhaps a better picture of the disillusioned intelligentsia of the day than any other U.S. novelist. Almost all nationalities appeared in his cast of characters, while Asia, Europe and New York served with equal effectiveness as his backgrounds. His earlier novels-The Seven. Who Fled (1937), Night of the Poor (1939) and The Conspirators (1943)-were better than his Idols of the Cave (1946), a sometimes vivid, too frequently diffuse, portrait of European refugee society in New York. Prokosch also showed himself to be a gifted poet, particularly in Death at Sea@(1940), in which he appeared to be outgrowing his overfascination with the style of W. H. Auden.

Three novelists who had first become notable during the early 1930s and who wrote little but well, continued to increase in stature. Josephine Herbst's Rope of Gold (1939) was perhaps the best of her left-wing fictional analyses of the middle class and a much more ambitious novel

Below, left to right: Authors of U.S. best sellers during 1937-46:
Margaret Mitchell (Gone With the Wind), William Saroyan
(Human Comedy), Betty Smith (A Tree Grows in Brooklyn), John
Steinbeck (Of Mice and Men; Grapes of Wrath; The Moon is
Down), Gladys Schmitt (David the King)

than her slight, deft, Satan's Sergeants (1941). Albert-Halper's The Chute (1937), although more diffuse than his earlier proletarian novel, The Foundry (1934), was a measured social criticism of the mailorder industry, while Sons of the Fathers (1940), a sympathetic treatment of first generation immigrants who became storekeepers, and Only an Inch From Glory (1943), a book about the little men of the middle class, extended his range of subject matter and showed an increasing mastery of a more economical style. Despite the fact that she was largely neglected by the public that had read Now in November (1934) avidly, Josephine Johnson continued to develop her great talent for saying much in short books. Her Jordanstown (1937), a spare parable of the conflict between labour and capital, and Wildwood (1946), a taut novel about an adolescent's search for affection, put her in the forefront of those writers of fiction who preferred suggestion to inundation in detail.

The most considerable novelist of the depression generation, Thomas Wolfe, was beginning to write more economically in his still too long You Can't Go Home Again, which was published the year after his death in 1939. In it, he renamed his chief character Monk Webber and retraced Eugene Gant's progress through the period covered in Of Time and the River (1935)-in other words, he rewrote the latter half of his slightly fictionalized autobiography. With the possible exception of Look Homeward, Angel (1929), it was his best novel, an eloquent book that was as full of a multiplicity of things, people and ideas as Whitman's poetry. It was about himself, his country, America's relation to Europe, the start of fascism, American literature and criticism, eating, sex and death, all magnificently communicated by a man who had perhaps the most sensitive sensory equipment of anyone who had ever written in the U.S. His earlier The Web and the Rock (1939) and the posthumously published The Hills Beyond (1941) were inferior fiction and did not add to the reputation his other books justly earned.

Another southerner who did not go home again was William March; his poorest novel, Company K, had enjoyed some popularity in 1933. Rarely a popular writer, March's psychological and social exploration of the south in such novels as The Tallons (1936) and The Looking Glass (1943), in short stories as those collected in Trial Balance (1945), was more artfully integrated than that of either Wolfe or Faulkner, although his scope was more restricted than Faulkner's and his gusto for experience was smaller than Wolfe's. Another neglected novelist of talent was Oliver La Farge. His too little read The Enemy Gods (1937) was quite as good as his Pulitzer prize winning Laughing Boy (1929), while his auto-

biography, Raw Material (1945), indicated that he was aware of the defects of his earlier fiction and might do still better work in the future. His brother, Christopher La Farge, who had usually been ranked as a popular fiction writer, turned out one of the best novels of 1946, The Sudden Guest, a complex and compelling psychological study of an egocentric woman that was also a fable of the insensitiveness of the comfortable American classes. All three of these novelists did better work than the more popular John O'Hara. The latter's swiftly moving mordant Appointment in Samarra (1934) had promised much more than the slick cynicism of such novels as Hope of Heaven (1938) and Pal Joey (1940) fulfilled.

New Novelists of the Decade.—Many promising novelists began what might become distinguished careers between 1937 and 1946. From close perspective, Robert Penn Warren, the southern poet, critic and novelist, seemed to have the greatest stature, but he was closely followed by Richard Wright, Gladys Schmitt, Charles Jackson and other novelists of indubitable talent.

Robert Penn Warren first attracted critical attention with his rapidly paced book about the tobacco wars in Kentucky, Night Rider (1939). At Heaven's Gate (1943), which centred upon the contrast between plutocracy and poverty in a large southern city, and All the King's Men (1946), an illuminating social novel about the life, death and influence of a Huey-Long-like politician, confirmed the judgment of his earlier critics. Selected Poems (1944) showed him to be one of the more gifted of the younger U.S. poets as well.

Richard Wright's *Uncle Tom's Children* (1938), a group of five novelettes about interracial conflicts in the south, did not attract the attention it merited, but *Native Son* (1940), the story of Bigger Thomas' socially fated fall, became a big best seller. *Black Boy* (1945), which told of Wright's experiences while he lived in the south, cemented the author's popular and critical reputation. Certainly one of the better North American novelists by any standard, Wright was clearly the most disciplined and gifted Negro craftsman in fiction, although Zora Neale Hurston and Arna Bontemps, of an earlier generation, approached his level in some of their books. The first novels of Chester Himes (*If He Hollers, Let Him Go*, 1945) and Ann Petry (*The Street*, 1946) also manifested a talent and a craft that closely approached Wright's.

Gladys Schmitt, Charles Jackson and Walter Van Tilburg Clark, all three of whom were praised for their first novels, disappointed some intelligent critics with their second books. The Lost Week-End (1944), a brilliant fictional study of drunkenness, was better received by both public and critics than Jackson's tale of the development of latent homosexuality in a middle-aged man in The Fall of Valor (1946). Gladys Schmitt's David the King (1946) seemed to many less impressive as a recreation of biblical history than her Gates of Aulis (1942) had been as a revelation of one of the major problems of the time-the conflicting importance of individual and social morality. The City of Trembling Leaves (1945) was acknowledged to be a more ambitious essay in fiction than Clark's The Ox-Bow Incident (1945), a philosophic novel about frontier justice, but the sprawling form of the second half of the later novel alienated many reviewers. It was generally agreed, however, that Clark, Miss Schmitt and Jackson-even at their not-bad worst-were promising fiction writers.

A number of other women writers seemed nearly as promising as Miss Schmitt to capable judges. Dorothy

Baker, whose Young Man With a Hoin (1938) had been called the best novel about a swing musician yet written and whose Trio (1943) was surely one of the most delicate treatments of homosexuality that an American had written, deserved more attention than she received. So did Carson McCullers with her excellent novel about a 13 year old girl who felt she did not "belong" to her family, The Member of the Wedding (1946). This was a tauter, better told novel than her earlier, more successful The Heart Is a Lonely Hunter (1940) and Reflections in a Golden Eye (1941). Helen Howe's sympathetically severe satire of intellectuals in The Whole Heart (1943) and We Happy Few (1946) deserved the acclaim it got from public and critics. Marjorie Kinnan Rawlings' expert short stories of the Florida country in When the Whippoorwill (1940) seemed to be underrated, while her novel The Yearling (1938) was perhaps overpraised. Christine Weston, after writing a number of inferior novels, won critical and popular success with her excellent novel about modern India, Indigo (1944), but her best-selling The Dark Wood (1946) seemed inferior to the more severe reviewers. Any one of these women might become as good novelists as Willa Cather or Edith Wharton.

Of the others who wrote a good many novels during the late 1930s and early 1940s, Conrad Richter, Meyer Levin, J. P. Marquand and Hamilton Basso all looked as though they might become important figures in modern American fiction. J. P. Marquand was most secure with the reading public, least secure with the critics. His The Late George Apley (1937) was undoubtedly a vivid and perceptive treatment of the conflict between the older and younger generations in modern New England, but such later books as Wickford Point (1939), H. M. Pulham, Esq. (1941) and B. F.'s Daughter (1946) seemed to many to be slight variations upon the theme of his first serious povel

Although he was only occasionally popular, Conrad Richter became during the decade the most highly praised American historical novelist apart from Howard Fast and Kenneth Roberts. His novels of frontier life-The Sea of Grass (1937), The Trees (1940) and The Fields (1946) were economically conceived and authentically based upon unromanticized history. Meyer Levin, in The Old Bunch (1937) and Citizens (1940), wrote perceptively of Jewish life in Chicago, Ill., and of the impact of left-wing movements on sensitive Chicago intellectuals. Although his scope was not as great as that of Farrell and his mastery of his medium was not as thorough as that of Nelson Algren (whose Never Come Morning [1942] was perhaps the most exciting and poetic novel that had come out of Chicago about the underprivileged) he promised exceedingly well. So did Hamilton Basso, who, however, seemed to be abandoning the novel for criticism in such books as Mainstream (1943), an account of seminal American ideas. In any event, his novel about New Orleans in Mardi Gras time, Days Before Lent (1939), one of the few modern novels that combined fast action with good thinking, and Sun in Capricorn (1942), one of the better modern novels about political demagoguery, deserved to rank with all but the best fiction of the time.

Of the first novelists of the decade 1937-46, there were a number whose later work might or might not confirm the high promise of their few but excellent first published works: Paul Goodman (The Facts of Life, 1945; The State of Nature, 1946); Mary McCarthy (The Company She Keeps, 1942); Jean Stafford (Boston Adventure, 1944); Elizabeth Hardwick (Ghostly Lover, 1945); Marguerite Young (Angel in the Forest, 1945); Jo Sinclair (Waste-

land, 1946); Bucklin Moon (The Darker Brother, 1948); Albert Maltz (The Underground Stream, 1940; The Cross and the Arrow, 1944); Saul Bellow (The Dangling Man, 1944); Frederick Wakeman (Shore Leave, 1944; The Hucksters, 1946); Mary Jane Ward (The Wax Apple, 1938; The Snake Pit, 1946).

Short Fiction.—Many of the novelists, like Ernest Hemingway and William Faulkner, were also superlatively good short-story writers. There were others during the decade, however, who confined their writing altogether to the short story or to the novella, or did their most successful work in this field. One of this latter group was Kay Boyle, who had earlier distinguished herself as a novelist with such books as Year Before Last (1932) and Gentlemen, I Address You Privately (1933). Her later novels, most of them about France, declined into propaganda, a genre she was ill-fitted to write. Her best work of the decade was in the group of long stories about maladjusted young people, The Crazy Hunter and Other Stories (1940) and in her collection, Thirty Stories (1946).

The irrepressible William Saroyan, who rivalled Upton Sinclair in both the quantity of his work and in his inability to criticize himself, did his best with the short story. There were good short tales about the melancholy-happy, adolescent-adult people in whom Saroyan specialized in all of his numerous collections, but the best of them were probably to be found in Little Children (1937) and Love, Here Is My Hat (1938). His plays and his mawkishly sentimental novels, The Human Comedy (1943) and The Adventures of Wesley Jackson (1946), were overpraised by softhearted critics and sold well, but they were not up to the sometimes excellent short stories or to the collection of sketches about childhood that were grouped loosely together in My Name Is Aram (1940).

Eudora Welty wrote two novels, The Robber Bridegroom (1942) and Delta Wedding (1946), but neither merited the praise which her two collections of short stories about Mississippi life, A Curtain of Green (1941) and The Wide Net (1943), deserved and received. These firmly wrought stories were securely set in a region, but Miss Welty's Negroes, salesmen and old maids were sufficiently universal to interest people who cared nothing about Mississippi. Caroline Gordon also wrote two novels -None Shall Look Back (1937) and Green Centuries (1941)—that did not have the quality of her superlatively good short stories, collected in The Forest of the South (1945). In these short tales her south became a symbol of a slower, more graceful, more hedonistic way of life than that common to the north, but Miss Gordon constantly avoided sentimental nostalgia by making readers aware that her region was tragically surrounded and enveloped by a more vital and crass "civilization."

One of the best of short-story writers, Dorothy Parker, wrote almost nothing during the decade, but the few stories about the Spanish civil war she added to Here Lies. The Collected Short Stories (1939) were among the best short fiction of the period. Her command of the taut, sophisticated story was rivalled by two New Yorker writers, Irwin Shaw and John Cheever. Particularly in his first collection, Sailor Off the Bremen and Other Stories (1939), Shaw proved that it was possible to combine slickness and emotional depth. His later collection, Act of Faith and Other Stories (1946), was also widely praised for the same qualities. Cheever's The Way Some People Live (1943) was particularly successful in conveying the seriousness of the problems of adolescents and of young people in love. One of the stories in the volume, "Of Love, a Testimony," was as good a short story as the decade produced.

By far the most exciting talent in the field of the short story and novella was Katherine Anne Porter. Her three collections—Noon Wine and Other Stories (1937), Pale Horse, Pale Rider (1939) and The Leaning Tower and Other Stories (1944)—established her in the foreground of the decade's literature. In such stories as "Old Mortality," an ironic-sympathetic account of the development of a romantic, and "The Leaning Tower," a story about the rise of fascism in pre-Hitlerian Germany, she managed to suggest more than most good novelists tell in detail.

Poetry

If one could judge altogether from sales appeal, it would seem that poetry was altogether negligible—as indeed some critics said. Only two poems of the decade, Stephen Vincent Benét's Western Star (1943) and Russell Davenport's My Country (1944), were even briefly on the best seller lists, and neither was regarded as particularly eloquent by competent critics. But good poems were being written and read by the discerning and it seemed probable to some competent judges that the decade would be best remembered for the many excellent poets who wrote for too few.

Frost's Generation.-Robert Frost was the only one of the poets already distinguished before World War I who appealed to both the critical and to a relatively large public—a Pocket Book selection from his poetry appeared in 1946. His balanced shuttling between the grave and gay, his preference for colloquial language and for the rhythms of ordinary talk, made him superficially easy to comprehend, although there was often profundity enough under the easily understood surface. Collected Poems (1939), A Witness Tree (1942) and A Masque of Reason (1946) maintained a level of excellence comparable to that of his earlier volumes, and the first two were awarded Pulitzer prizes. Of the many more minor figures who superficially resembled him, the most gifted and individual in his own right was undoubtedly David Morton, whose Selected Poems (1945) revealed a genuine talent.

Frost's closest rival for combined public and critical appreciation was Robinson Jeffers, a somewhat younger poet whose first volume had been published a year before Frost's first volume, A Boy's Will (1913). Jeffers' angry, pessimistic and unconventional view of life, which contradicted all current American imperatives, was expressed in a style that the public at least superficially comprehended and enjoyed. Critics felt that there was no question of the eloquence and integrity of Such Counsels You Gave To Me (1937), Be Angry at the Sun (1941) and The Medea, Freely Adapted (1946). They hailed his Selected Poetry (1938) as evidence of the major quality of his work.

During the decade, Edna St. Vincent Millay continued to get more sales than praise. Most serious reviewers thought her ideas about contemporary affairs in Conversation at Midnight (1937) confused and confusing and her Huntsman, What Quarry? (1939) inferior to her best lyrical poetry. There was almost unanimous agreement about the hasty conception and execution of Make Bright the Arrows (1940) and The Murder of Lidice (1942), in both of which Miss Millay's patriotic heart got away from the command of her intelligence. The publication of her Collected Sonnets (1941) and Collected Lyrics (1943) proved, however, that Miss Millay was a talent to be reckoned with when her poetic intelligence asserted itself.

Two other poets who had once commanded a relatively

large audience declined in both critical and public esteem. Edgar Lee Masters, whose Spoon River Anthology had been a sensation in 1915, published too much that he had not digested poetically. Probably the best of his five books of verse was The New World (1937), but even this was not as readable as his biographies of Whitman (1937) and Mark Twain (1938). Carl Sandburg, who only published a few—and inferior—poems in Homefront Memo (1943), did not suffer as sharp a decline as Masters, for his Abraham Lincoln, which he completed in 1939, was recognized by both the public and the intellectual elite as one of the great biographies of the time.

Other poets who had established reputations during the "poetic renaissance" that followed the establishment of Poetry: A Magazine of Verse in 1912, continued to develop their talents for a small, discriminating audience. One of the most gifted of these was Conrad Aiken, a poet who combined psychological perceptiveness and an ability to put emotions and ideas into varied and appropriate musical patterns. His And in the Human Heart (1940), a moving collection of love sonnets, and his poems of city life, Brownstone Eclogues (1942), were superior to his ambitious failure, The Soldier (1944), an attempt to epitomize the totality of soldier experience throughout all time. He also published an excellent short novel, Conversation (1940), a vivid telling of a marital quarrel.

John Gould Fletcher, who at one time influenced Aiken and was influenced by him, deservedly won the Pulitzer prize for his Selected Poems (1938), but most of his volumes during the decade did not add to his reputation. Too many of them were diffuse narratives about his native state of Arkansas, such as those included in South Star (1941), but there were some superior tone poems, such as "Symphony of Snow" in The Burning Mountain (1946). Fletcher's autobiography, Life Is My Song (1937) was a movingly honest document and, with Harriet Monroe's A Poet's Life (1938), one of the best accounts of the renaissance that took place before World War I.

Two other participants in this renaissance enhanced their reputations during the decade. H. D. (Hilda Doolittle), who had been called the one pure imagist, showed herself in full command of her power to evoke emotion by her subtle free verse movement and by her fresh imagery in The Walls Do Not Fall (1941), while Alfred Kreymborg, unjustly neglected, proved that he deserved serious readers by the publication of Selected Poems (1945) and his wisely reflective poem, Man and Shadow (1946).

Although Ezra Pound's reputation as a poet was outweighed by his preference of Italian fascism to American democracy in the minds of many, he remained an important force in American letters by his publications in both poetry and prose. His controversial yet stimulating Culture (1939) and Polite Essays (1940) were carefully thought-out attacks on the established ideas about what makes a cultivated man, while his excessively difficult The Fifth Decad of Cantos (1937) and New Cantos (1940) were nevertheless considered interesting experimental verse by competent critics. A more lucid than usual canto appeared in the Sept. 1946, issue of Poetry, a magazine he did much to make into the vital force it had become in modern poetry, along with two appreciative essays by T. S. Eliot and R. P. Blackmur.

William Carlos Williams, a poet who was for some time associated with Pound in the early days when imagism was an important movement in modern verse, published much and well during the decade. His Collected Poems (1938)

revealed his unsurpassed ability to make poetry out of objects sharply seen and sharply expressed. The Broken Span (1941), The Wedge (1945) and, most of all, Paterson: Part One (1946), showed that his talent continued to develop. He also published a volume of short stories, Life Along the Passaic River (1938), and two novels, White Mule (1937) and In the Money (1940), books that further established his competency as an observer and interpreter of American life.

Two more conventional but able poets who started to publish before World War I continued to print good poems during the decade. Louis Untermeyer's activity as an anthologist tended to overshadow his work as a poet, but he published a competent translation of Heine (Heinrich Heine, Paradox and Poet) in 1937 and an autobiography that illuminated the development of modern poetry as well as his own life, From Another World (1939). Robert Hillyer's finished, soberly reflective, poetry, conservative in both substance and form, was at its most mature in A Letter to Robert Frost (1937), In Time of Mistrust (1939) and Pattern of a Day (1940).

Post-World War I Poets.-The idiom of T. S. Eliot, one of the great poets of the century, was adapted after World War I by a large number who did not share his views. Although the older poet's influence was more heavily apparent in Archibald MacLeish's earlier verse, Eliot's way with language and with unifying, unusual figures continued to influence MacLeish's publications during the 1930s. But MacLeish, like many of the poets of the decade, did not so much imitate Eliot as adopt his poetic devices. Certainly the matter of Public Speech (1936), Land of the Free (1938) and America Was Promises (1939) was MacLeish's own variety of social liberalism, while both the manner and matter of his radio plays in verse, The Fall of the City (1937) and Air Raid (1938), proved that he had assimilated Eliot and his other poetic ancestors.

Among the other post World War I poets who spent part of their poetic adolescence absorbing Eliot's technique were such diverse talents as John Peale Bishop, John Crowe Ransom, Marianne Moore, Wallace Stevens, Mark Van Doren, Louise Bogan, Genevieve Taggard and Allen Tate. Of these, Bishop, whose Selected Poems (1941) was his single publication in the decade during which he died, was the most derivative, but there were poems in this volume, particularly his elegiac poems, that succeeded in their own right.

Although he published a good deal of excellent criticism and edited the valuable Kenyon Review, John Crowe Ransom published poetry as sparingly as Bishop. His Selected Poems (1945), however, showed a poet who was too self-critical to allow anything merely derivative to enter his published work. In their deft intermingling of the tragic and the humorous, in their always effective and always present irony, they ranked among the most effective poems of the period.

Ransom's friend and co-worker in the earlier Fugitive group in Nashville, Tenn., Allen Tate, showed a similarly ironic awareness of the complexity of experience in his Selected Poems (1937) and The Winter Sea (1944), but he was usually more obscure and frequently a less sure judge of his own excellence than was Ransom. Though he usually seemed to be a less original poet than Tate, Mark Van Doren's frequent excellence was obscured by similar defects, as his Pulitzer prize winning Collected Poems (1939) revealed. His slim pamphlet volume, Our Lady Peace and Other War Poems (1942), appeared to reveal a more sure mastery of metaphysical practice and was cer-

Deer (1941).

Marianne Moore, with her syllabic metrics and her unusually effective use of symbolic animals as integrating devices, published some of the outstanding poetry of the decade. What Are Years? (1941) and Nevertheless (1944) were slender in size but large in quality. It is doubtful if any poet published a more effectively complex, yet moving, war poem than her "In Distrust of Merits" which appeared in the latter volume. Louise Bogan also published sparingly and well. Her The Sleeping Fury (1937) communicated an unusual sense of the beauty of intellection, while her Poems and New Poems (1941) revealed an intellectual ardour similar to that found in the later poetry of William Butler Yeats. Genevieve Taggard, another woman poet, combined a social leftism with a fondness for metaphysical devices. Her Collected Poems (1938) and Slow Music (1946) contained excellent poems, though these were too frequently buried beneath the mass of mediocre verse she allowed herself to publish.

With the possible exception of Ransom, Wallace Stevens was the most original of the poets who were once affected by Eliot's style. Since he was constantly preoccupied with the philosophical problem of the relation between reality and appearance, between the image and the thing symbolized, he was not a popular poet. There were not, however, many poets, ancient or modern, who had written more rewardingly of these themes than Stevens did in The Man with the Blue Guitar (1937), Notes Toward a Supreme Fiction (1942) and Parts of a World (1942), volumes in which he managed to give concrete form to philosophical concepts with rare felicity.

E. E. Cummings, who showed no trace of influence by the substance of either Stevens or Eliot, seemed to many to be original to the point of eccentricity. However, after readers and critics had gradually accustomed themselves to his apparently queer typography, he became increasingly recognized for the serious and distinguished poet he was. His Collected Poems (1938) revealed him as one of the most adept satirical and lyrical poets of the period and as one of the most insistent propagandists for living the good life of the senses. In his later Fifty Poems (1940) and I Times I (1944), he still further developed his original style by his unusual and effective use of verbs and indefinite pronouns, while his Santa Claus: A Morality (1946) showed that he was able to write as clearly as a more conventional poet.

Cummings was more likely to intrigue readers of the future than was one of the most conventional and popular poets of the decade, Robert P. Tristram Coffin, who published almost as steadily as Edgar Guest and sometimes descended to the latter's level of infelicity. In Collected Poems (1939), Primer for America (1943) and Poems for a Son with Wings (1945), Coffin spread himself too thinly over the entire American continent he had taken for his poetic province, but there were some poems about the Maine country and about his son that would earn him a higher reputation if they were selected and published separately. William Rose Benét and his brother, Stephen Vincent Benét, who died in 1943, would benefit similarly from careful anthologizing. They too took everything in America as their province and often came up with commonplace ideas and emotions that were tritely expressed. William Rose Benét's Pulitzer prize winning poetic autobiography, The Dust Which Is God (1941) was honest, illuminating and uneven. It was far superior to his often hysterically patriotic verse in Day of Deliverance (1944). The work of Stephen Vincent Benét was more individual,

and his long narrative, Western Star (1943), almost attained the excellence of his earlier John Brown's Body (1928). The verse in The Ballad of the Duke's Mercy (1939) and in The Last Circle (1946) was only occasionally successful, since Stephen Benét did not seem to have the ability to compress his substance into a short poem. Some good short stories, most of them about historical subjects, appeared in his volumes, The Last Circle, Thirteen O'Clock (1937) and Johnny Pie and the Fool Killer (1938).

None of these moderately popular, conventional poets did work of as high a quality as that of Witter Bynner, who had been publishing from 1907 but had not gained a reputation until the publication of his Selected Poems in 1936. Against the Cold (1940), his one volume for the decade, maintained the high level of vivid succinctness he had frequently reached in his own poems and in his admirable translations from the Chinese.

Whatever one may think of the success of their verse, it was undoubtedly true that Coffin and the two Benéts were honestly concerned with making American democracy work. Their work in this direction was surpassed, at least poetically, by the activity of a number of younger, unhappily less popular, poets: Langston Hughes, Paul Engle, Kenneth Fearing and Horace Gregory. Hughes published only one volume of poems, Shakespeare in Harlem (1945), during the decade, but that volume, in its effective use of blues rhythms to convey the troubles of Negroes, marked a clear advance above his earlier work. He also published an autobiography, The Big Sea, in 1940, which was an important help to understanding the Negro's justified dissatisfaction with his position in North American society.

Paul Engle, whose American Song (1934) was one of the more eloquent pleas for the democratic way, restricted his scope somewhat in the Iowa poem, Corn (1939) and in American Daughter (1945), but he showed an increasing mastery of form in these later volumes, both of which were more effective technically than his early Sandburgian verse. A more negative poet, who also tended toward the loose Sandburgian line, Kenneth Fearing increased his reputation as a critic of the abuses of democracy and as a singer of the loneliness of the average man. His Collected Poems (1940) were usually moving and always readable, while his Afternoon of a Pawnbroker (1943) showed that he was capable of a more disciplined style without any loss of clarity or scope. Horace Gregory shared many of the concerns of Hughes, Engle and Fearing, but he showed himself to be both a more difficult and a more original craftsman. Poems: 1930-1940 (1940) belonged clearly in the Eliot-metaphysical tradition, but it also showed that Gregory had absorbed his ancestors and developed an individual style, particularly in his later monologues about disheartened average people. With his wife, Marya Zaturenska, he published the most comprehensive history of American poetry the century had seen, American Poetry: 1900-1940 (1946), a thoroughly accurate guide to the poetry of the first 20 years of the 20th century, but a somewhat more prejudiced guide to the next 25 years. Miss Zaturenska (or Mrs. Gregory) revealed a good eye and a good ear in the reflective-descriptive poems that appeared in her Pulitzer prize winning Cold Morning Sky (1937), in Listening Landscape (1941) and in The Golden Mirror (1944).

Poets of the Decade.—Most of the poets whose reputations were largely or wholly made within the decade 1937-46, started out, at least, with a strong concern about the dangerous direction American society seemed to be taking.

Muriel Rukeyser, whose Theory of Flight had been hailed as an exceedingly promising volume when it appeared in 1935, was one of the most gifted and certainly the most prolific of these younger poets. In US 1 (1938), A Turning Wind (1939) and The Soul and Body of John Brown, she showed an uneven gift for revealing the interpenetration of the social and the personal in a metaphysical idiom that owed a good deal to the work of both Eliot and W. H. Auden. In her later Beast in View (1944), the style was more individual and the successful poems were more frequent. Miss Rukeyser was also the author of one of the best biographies of the decade, Willard Gibbs (1942).

Almost all of the poets who emerged as important talents shared Miss Rukeyser's admiration for the style of Auden and the Oxford poets, all of whom had felt the influence of Eliot. Because of the industrial background they shared and because of the influence of Auden, Stephen Spender and Louis MacNeice, all these young American poets wrote about factories, aeroplanes and city life with the same natural fascination with which 19th century poets had written of galleons and flowers. Like their British contemporaries, too, they wrote in a style that approximated the slangy-colloquial speech that was becoming increasingly common among even intellectuals, though they did not find this language incompatible with the exhibition of a great deal of metrical dexterity in the manipulation of a wide variety of conventional verse forms.

Karl Shapiro was the most widely praised and read of these young American poets. In Person, Place and Thing (1942) and V-Letter and Other Poems (1944), he wrote vividly and understandably of air raids, dead soldiers, movies and war-torn life generally with a penetration that transcended the contemporary subject matter. As his uneven Essay on Rime (1945) revealed, he had thought much and well about both the past and the possible future of poetry, and it seemed likely that he would completely outgrow all of his influences to become that unusual phenomenon, a poet who thinks and feels deeply yet communicates with absolute clarity. His closest rival among those who published at all frequently was Delmore Schwartz. His In Dreams Begin Responsibilities (1940), although it revealed the influence of the Oxford group, was particularly original in its use of a multiple focus in the dream play, Coriolanus. In Shenandoah (1941) and Genesis (1943), he wrote two long narratives that made effective poetic use of the Freudian insight that the child fathers the man.

Equally preoccupied with the interrelation of society and the individual and equally affected by the Oxford group and Eliot but somewhat less clearly original were Randall Jarrell, Jeremy Ingalls, Richard Eberhart, Thomas Merton, Robert Lowell, John Malcolm Brinnin, John Ciardi, Weldon Kees, John Frederick Nims, Dunstan Thompson and Oscar Williams. Randall Jarrell, who published Blood for a Stranger in 1942 and Little Friend, Little Friend in 1945, wrote movingly about World War II and the psychological environment from which it grew, but he also wrote too frequently with an almost wilful obscurity. Jeremy Ingalls' first volume, The Metaphysical Sword (1941), shared both the faults and the virtues of Jarrell's books, but her ambitious Tahl (1945), a long and sometimes successful narrative-philosophic poem, was frequently dull as Jarrell's books never were.

A dull diffuseness was also sometimes evident in The Lincoln Lyrics (1942) and No Arch, No Triumph (1946) by John Malcolm Brinnin. In working toward an individual style, which he sometimes achieved, he frequently lost the liveliness that characterized his earlier Audenesque; The Gurden Is Political (1941). Assuredly he seemed a less gifted poet than the frequently difficult, always interesting, Richard Eberhart. In Song and Idea (1940) and Poems New and Selected (1944), Eberhart wrote some of the best of the many poems about death and showed himself to be a constantly developing stylist. In The Man Coming Toward You (1940) and That's All That Matters (1945), Oscar Williams showed a similar capacity for stylistic growth and combined the idiom and substance of Auden with a modification of surrealist technique in some of his more effective poems.

Of quite different substance but of similarly derived styles were the three Catholic poets: Robert Lowell, Thomas Merton and John Frederick Nims. Robert Lowell, for his Land of Unlikeness (1944) and Lord Weary's Castle (1946), had easily the most distinguished reputation. His intensely bitter and passionately eloquent worldly and religious poems were something altogether new in the religious poetry of the 20th century, though they showed the influence of Auden, Hopkins and the surrealists. Thomas Merton's Thirty Poems (1944) and A Man in the Divided Sea (1946) were more derivative and more rarely eloquent, but there were many satisfying poems in both volumes. Despite the fact that he had only appeared in Five Young American Poets (1944), an interesting publishing experiment in which the "books" of five poets were included under one cover, John Frederick Nims seemed to some critics the equal of Lowell. Certainly no one had published more savagely successful satire than his "Dollar Bill" and "Apocalypse."

Like Nims, the other three poets affected by Auden and the Oxford group published little, but their little promised well. John Ciardi, who published Homeward to America in 1940, was perhaps the most gifted of the three, for he was able to write both lyrically and satirically with great effectiveness about subjects as varied and modern as those of Shapiro. Dunstan Thompson, in Poems (1943), was more uneven, but his elegiac poems were among the best written during the war years. Weldon Kees was at his best in satire and there were many good, biting poems in The Last Man (1943).

In this singularly rich poetic decade, there were many poets with less obviously determinable ancestors who might become as good or better than the poets just discussed. Kenneth Patchen was surely the most frequently printed poet of the decade, but his work was selected so uncritically that the early reputation he won with Before the Brave (1936) was almost lost. His Selected Poems (1946), culled from the six books he had issued earlier. re-established him as a gifted lyric and satirical poet, although even here there was too much that sounded more like Henry Miller versified than like Kenneth Patchen. He also published a number of surrealistic works in prose, of which The Memoirs of a Shy Pornographer (1944) was, oddly, the least shocking and the most interesting.

Kenneth Rexroth was probably a better poet. In What Hour (1940) and The Phoenix and the Tortoise (1944) contained many excellent lyric, reflective and erotic poems, but it was in the latter category that Rexroth most clearly matured his individual talent. In the sometimes derivative Wind the Clock (1941) and the unusually vivid narrative of Thomas Dorr's rebellion, The Sword on the Table (1942), Winfield Townley Scott also revealed a talent that could express itself in various media. Similarly varied were the talents of Rolfe Humphries in Out of the Jewel (1942) and of Robert Fitzgerald in A Wreath for the Sea

(1944), though Humphries' original gift was overshadowed by his reputation as a translator from the Spanish, and Fitzgerald's still more considerable talent was obscured by his unique excellence as a translator from the Greek.

Of the considerable number of other poets who published infrequently during the decade, all of the following were highly praised by discerning critics: Alfred Hayes (The Big Time, 1944); Josephine Miles (Local Measure, 1946); Jon Beck Shank (Poems, 1945); Ruth Lechtliner (Only the Years, 1945); James Laughlin (Some Natural Things, 1944); Theodore Roethke (Open House, 1942); Jean Garrigue (Thirty-Six Poems and a Few Songs, 1944; The Ego and the Centaur, 1946); Theodore Spencer (The Paradox in the Circle, 1941; Act of Life, 1944); Marguerite Young (Moderate Fable, 1944); Howard Nutt (Special Laughter, 1940); Clark Mills (Speech after Darkness, 1942; The Circus, 1945); Hortense Flexner (North Window, 1943); Elizabeth Bishop (North and South, 1946); Babette Deutsch (One Part Love, 1939; Take Them, Stranger, 1944); R. P. Blackmur (From Jordan's Delight, 1937). It was quite impossible to exclude from any account of the poetry of the decade the amusing, sometimes meaningful, usually too prolix Ogden Nash, whose The Face Is Familiar (1940) was a selection of his best verse. (See also POETRY.)

Literary Criticism

Allied to poetry in both its usual excellence and in its usual failure to find many readers was the field of literary criticism. Van Wyck Brooks, however, managed to combine critical distinction with great popular appeal in two successors to the best-selling Flowering of New England (1936). New England: Indian Summer (1940) continued his familiar method of blending history, biography and a minimum of critical judgment in order to recreate the atmosphere in which the writers themselves lived. So did The World of Washington Irving (1944), although neither the critics nor the public received this volume with as much enthusiasm as they had accorded to the two predecessors. During the decade he also published The Opinions of Oliver Allston (1941), a sometimes ill-tempered book in which he assailed many "great" later writers for their decadence and thereby showed what some critics had suspected from his otherwise fine literary history: Brooks was not as sensitive to literary values as he was to moral values.

His closest rival in popularity was Bernard De Voto, who also published an ill-tempered attack upon writers who reflected the disillusionment of the 1920s and early 1930s-The Literary Fallacy (1944). In his Mark Twain at Work (1942) and The Year of Decision (1943), he made distinguished and temperate contributions to the history and literature of the 19th century. Henry Seidel Canby's critical biographies were as justly popular as De Voto's excursions into literary history and history. Thoreau (1939) and Walt Whitman (1943) were generally acknowledged to be definitive critical biographies, thorough in scholarship and in appreciation. Equally valuable as criticism and somewhat above the average in popularity were the books published by Jacques Barzun. Darwin, Marx, Wagner: Critique of a Heritage (1941) and Romanticism and the Modern Ego (1943) were excellent studies in the background of modern thought, while Teacher in America (1945) was surely the most engaging and possibly the most valuable of the host of books about the deficiencies of modern education that appeared during the decade.

It was rather doubtful, however, if any of these critics would be read as long or as thoroughly as Edmund Wilson. A gifted creative writer in his own right (the much-dis-

cussed Memoirs of Hecate County, 1946) and the book editor of the New Yorker, Wilson had an unusual ability for combining literary and sociological perceptiveness. His studies of such older writers as Dickens and Kipling in The Triple Thinkers (1938) and The Wound and the Bow (1941) were quite as discerning as his early book on the symbolist movement, Axel's Castle (1931), while his history of the development of socialist thought, To the Finland Station (1940), despite its occasional unnecessary acrimony, was one of the best works in intellectual history printed during the decade. His study of the hard-boiled school of American writers, The Boys in the Back Room (1941), was a valuable, though sometimes dubiously subtle, addition to the criticism of literature.

In many ways an equally gifted critic, though his early The Great Tradition (1933) had been overly orthodox in its Marxism, Granville Hicks published only one work of specific literary criticism during the decade. This book, Figures of Transition (1939), a study of end-of-the-century writing in England, was notable for its admirable relating of intellectual and social history to literary value, and stood as one of the decade's best studies of English literature. Hicks' other publications during the period included three good novels (The First to Awaken, 1940; Only One Storm, 1942; Behold Trouble, 1944) and two interesting combinations of autobiography and sociology, I Like America (1938) and Small Town (1946).

Like the critics already discussed, Newton Arvin was more interested in intellectual and social values in literature than in aesthetic exploration. His Whitman (1938) was by far the best study of the poet's thought yet written, while his edition of Hawthorne (1946) was a model of critical intelligence. Among the other able works of criticism stressing intellectual and social values were Bernard Smith's Forces in American Criticism (1939), Eric Russell Bentley's examination of the writers who wrote of the superman, A Century of Hero Worship (1944) and The Playwright as Thinker (1946), Maxwell Geismar's book on contemporary literature, Writers in Crisis (1943) and Alfred Kazin's survey of American prose literature, On Native Grounds (1942). Another able student of American literature and ideas, Howard Mumford Jones, published only one book that was definitely concerned with the American literary scene, Ideas in America (1944), but he also published a first-rate biography of Thomas Moore, The Harp that Once ... (1937) and a provocative study of the insularity of the literature curriculum in the American college, Education and World Tragedy (1946).

The most original, influential—and sometimes the most pretentiously esoteric-school of criticism of the decade centred about such little magazines as The Southern Review and The Kenyon Review, periodicals published at U.S. colleges and edited by men of letters who were also professors. The gifted poet, John Crowe Ransom, editor of The Kenyon Review, was perhaps the most talented of the group. In his collection of critical essays, The World's Body (1938) and his examination of the basic ideas in modern criticism, The New Criticism (1941), he showed an unusually subtle, though sometimes overdogmatic, grasp of the complexity of the artistic experience. His essay on metaphysical poetry in The World's Body, together with the book of his co-editor, Cleanth Brooks, Modern Poetry and the Tradition (1939), was basic to an understanding of modern poetic theory and practice.

Most of the contributors to these magazines shared Ransom's convictions about the literary process and were sim-

ilarly astute and close critics. The poet, Allen Tate, in his Reason in Madness (1941), and the critic, R. P. Blackmur, in his admirable The Expense of Greatness were among the most gifted of the critics of this school. They applied the ideas they shared in common with individual acumen to a variety of contemporary and precontemporary writers. A similarly close critic, Yvor Winters, shared with these southern reviewers a concern for careful, subtle reading, but he also shared with such earlier critics as Irving Babbitt and Paul Elmer More a great concern for the moral impact of literature. In Primitivism and Decadence (1937), Maule's Curse (1938) and Edwin Arlington Robinson (1946), he pursued his enemy, the romantic idea, with intelligence and somewhat too much zealotry.

Kenneth Burke, a more powerful and a more unclassifiable critic than any of the southern reviewers with whom he was frequently published, wrote illuminatingly about history, sociology, literature and psychology without ever forgetting the interrelationships among the four. In Permanence and Change (1937), Attitudes toward History (1937), The Philosophy of Literary Form (1941) and A Grammar of Motives (1945), he erected a system that combined many of the best insights of the southern reviewers, the Marxists, the Freudians and the semanticists.

There were other excellent critics who were not as difficult to understand as was the school loosely grouped around Ransom. Lionel Trilling's critical biography, Matthew Arnold (1939) was a study of a key figure in the 19th century who remained an important influence upon the 20th, while his E. M. Forster (1943) could serve as a model of what the good critical biographer should do. An equally important and equally lucid critical biographer of the decade was F. O. Matthiessen. He had already established his reputation as a critic who understood the importance of a man's times, life and theory of art in the creation of his work, in The Achievement of T. S. Eliot (1940); but his American Renaissance (1941), a study of the flowering of New England that surpassed Van Wyck Brooks' work in critical depth, and his critique of the later novels of Henry James (Henry James, the Major Phase, 1944) definitely established him in the foreground of American criticism. With him in their sense of the multiple factors that go to make up the effective work of art were Mark Schorer, who published his definitive William Blake in 1946 and Herbert Muller, whose Modern Fiction (1937) was perhaps the best study of the modern novel that had yet been published and whose Science and Criticism (1943) was both well informed and a suggestive basis for the further development of a criticism that was indebted to but not subservient before modern science.

Biography and Autobiography

Much of the criticism discussed above was biographical, while much of the so-called pure biography of the decade 1937–46 was mixed with a great deal of social, historical and literary criticism. The difference lay in the emphasis. Biographical information was incidental to critical appraisal in such a book as Lionel Trilling's E. M. Forster; in such a book as Joseph Wood. Krutch's Samuel Johnson (1944), critical evaluation was secondary to a full revelation of the life of the man. Krutch's biography of Samuel Johnson was generally regarded as one of the best biographies of a literary man published during the decade.

Probably Carl Van Doren's Benjamin Franklin (1938) was similarly definitive. Van Doren uncovered a great deal of new information about the public and private life of

Franklin and saw him as neither god nor devil. Van Doren also published *The Secret History of the American Revolution* (1941), important for its new data and new interpretation.

Whether Herman Hagedorn's Edwin Arlington Robinson (1938) or Philip Horton's Hart Crane: the Life of an American Poet (1937) were as definitive as the biographies of Krutch and Van Doren was difficult to say. Although as a critical evaluation of the poetry it was inferior to Yvor Winters' short Edwin Arlington Robinson (1946), there could be little doubt that there was no better biography of Robinson available than Hagedorn's sympathetic but perhaps too reticent account of the life of his friend. A more judicious mixture of biography and criticism, Horton's Hart Crane was a thoroughly scholarly life of one of America's most interesting poets.

The two biographies written by Matthew Josephson were usually adjudged illuminating by the critics, although there were some who felt that Josephson was not as incisive as Horton and Krutch. Josephson's Victor Hugo (1942) and Stendhal (1946) were unusually well adjusted to the taste of the general public, however, and brought many readers to the work of the men themselves. Probably Josephson was at his best in the continuation of the series of biographical panoramas he started with The Robber Barons (1934). The Politicos (1938) and The President Makers (1941) rounded out his severely critical portrait of what was perhaps the most corrupt period in U.S. history, the years between the death of Lincoln and the election of Theodore Roosevelt.

Catherine Drinker Bowen, the most popular biographer of the decade, was also one of the best. Her first success was the perceptive, well-informed, popularly written Beloved Friend (1937), an account of the relationship between Tschaikovsky and Nadejda von Meck. Yankee from Olympus (1944), a biography of Justice Oliver W. Holmes firmly set in the background of the distinguished Holmes family, was high on the best-seller lists for more than a year. It was a remarkable example of biography that managed to please the public without any sacrifice of critical integrity or factual accuracy. It was likely, though, that her biographies were not as comprehensive or as definitive as Marquis James' Andrew Jackson: Portrait of a President (1937) or Allan Nevins' John D. Rockefeller: the Heroic Age of American Business (1940). Nevins' biography was, however, frequently criticized.

Of the numerous autobiographies produced during the decade, none combined excellence and popularity more effectively than Clarence Day's amusing, serious and illuminating Life with Mother (1937) and Life with Father (1936). Pierre van Paassen's quite different Days of Our Years, which topped the best-seller lists for 1939, was probably the most illuminating reporter's account of himself and his times that appeared. In its anticipation of the approaching war, it was a prophetic book, as well as a brilliant record of what Van Paassen had seen and felt and thought. An equally thoughtful but less popular book was Oswald Garrison Villard's telling of his life as a proponent of liberalism, Fighting Years (1939). In this autobiography, too, one could sense the inevitability of war and understand better the forces that made it inevitable. A similar illumination could have come from reading The Letters of Lincoln Steffens (1938), for these collected letters amplified and clarified the account of Steffens' growth to understanding of the contemporary world that he himself had given so brilliantly in the Autobiography (1931).

The most distinguished autobiographical writing of the decade was the series of volumes published by H. L.

Mencken and George Santayana. There was great contrast in their distinctions. Santayana's beautifully quiet prose, telling of a life in which ideas had been the main events, formed a marked antithesis to Mencken's polysyllabic Americanese, telling of a life in which conflict and shocking the public were outstanding. Mencken's as yet incomplete narrative about himself was contained in Happy Days (1940), Newspaper Days (1941) and Heathen Days (1943), while Santayana's similarly incomplete series about himself was found in Persons and Places (1944) and The Middle Span (1945). During the decade, Mencken also published the first supplement to his magnificent The American Language (1936) in 1945, while Santayana published one of his most important philosophic discourses, The Realm of Truth (1937), which, with John Dewey's Problems of Men (1946), ranked among the great works of 20th century philosophy.

The only other autobiographies of the decade that seemed reasonably sure to remain of permanent interest were those by Mabel Dodge Luhan, W. E. du Bois and William Alexander Percy. Mrs. Luhan's sometimes naive and always superlatively frank record of her intimate memories was continued in Edge of Taos Desert (1937), which contained some particularly valuable material about D. H. Lawrence. Percy's Lanterns on the Levee (1941) was the life story of a sensitive southerner's attempt to adjust to an increasingly Yankee-dominated world. It could usefully be read as a contrast to Du Bois's narrative of his difficult adjustment to a white man's world in Dusk of Dawn (1940).

History

Charles and Mary Beard still maintained their position as leaders of historians with a reasonable claim to regard as literary figures. Although America in Midpassage (1939), perhaps because of the close perspective from which the 1930s in the U.S. had to be viewed, was generally thought inferior to The Rise of American Civilization (1927), everyone agreed upon its excellence as history and as literature. There was less general agreement about the merits of Basic History of the United States (1940), in which the Beards seemed to have been overinfluenced by their growing preference for American isolation, while there were many who disagreed with Beard's Giddy Minds and Foreign Quarrels (1939) and A Foreign Policy for America (1940), books in which he emphatically disagreed with the growing American tendency to feel itself involved in European conflicts. There were few, however, who did not admire The Republic (1943), a winning series of dialogues about the theory and practice of American politics.

No one else of literary distinction was as prolific as the Beards, but there were a number of notable and wellwritten historical volumes published during the decade. Two of the best were about the south. Douglas Southall Freeman brought to a close his definitive Lee's Lieutenants in 1944, and W. J. Cash published his excellent The Mind of the South in 1941. Arthur M. Schlesinger Jr.'s The Age of Jackson (1945), a work written with a conscious eye upon the analogies between the age of Roosevelt and the age of Jackson, started with the south but included all America in its province. With The Triumph of American Capitalism (1940) by Louis M. Hacker, The Age of Jackson was probably the best historical work of great scope produced during the decade. There were, however, three works in U.S. intellectual history that equalled these two good books in quality. Constance Rourke's The Roots of American Culture (1942) was a basic study of the interrelationships between U.S. culture and folkways, written with great charm and grace. Merle Curti's Growth of American Thought (1943) was generally judged a worthy rival to Vernon Parrington's Main Currents in American Thought, while Ralph Barton Perry's Puritanism and Democracy (1945) was usually considered a definitive contribution to the history of American thought as well as a provocative work in philosophy.

Reportage.—Because of the increasing tension in world affairs throughout the decade and the increasing public curiosity about the international situation, reporters wrote and published more books than ever before. A good many of these were inferior, full of snap judgments and inadequate information, but there were more than a few with literary distinction. Vincent Sheean was still perhaps the most notable of these reporters, although he did nothing that was quite as good as his Personal History (1935), which had been widely acclaimed as one of the most thoughtful autobiographies of the century. In his later books, there was less of himself, more of world events. Not Peace But a Sword (1939), an able analysis of what was happening in pre-Munich Europe, was succeeded by Between the Thunder and the Sun (1943), an account of the early war years, and This House Against This House (1946), a less satisfactory analysis of the troublesome conflicts that continued after World War II.

John Gunther rivalled Sheean in the scope he covered, but most informed critics felt that there was a descending scale of excellence from his Inside Asia (1939) to his Inside Latin America (1941). His reputation was overshadowed by that of a number of war reporters, of whom Ernie Pyle was the most distinguished representative. In Here Is Your War (1943) and Brave Men (1944), the humble and eloquent Pyle managed to catch the mingled pathos, humour and heroism of the common soldier as it had never been caught before. The reportage of John Hersey was nearly as good. His story of the fighting on a Japanese island in the Pacific, Into the Valley (1943), and his mordant account of the bombing of Hiroshima (Hiroshima, 1946) were unusually perceptive, while his novel, A Bell for Adano (1944) was more interesting as a report of mismanagement in the military government of Italy than it was as a piece of fiction.

It was difficult to single out among the many others. Surely Ira Woolfert's Battle for the Solomons (1943) and Richard Tregaskis's Guadalcanal Diary (1943) deserved more than brief remembrance. So did William L. White's account of the horrible, problematically necessary, expenditure of some lives in war time, They Were Expendable (1942) and Bill Mauldin's Up Front (1945). It was probable, too, that William L. Shirer's Berlin Diary would be adjudged finally the best of the I-was-in-Germany-when books that flooded the market during the early 1940s.

Social and Cultural Criticism

The decade was rich in writers who made earnest and frequently successful attempts to convince the public that there were ways out of the seeming impasse western civilization reached in the years immediately preceding and during World War II. One was Max Lerner, editor of P.M. In It is Later Than You Think (1938), he called for a common front against totalitarianism, whether of the right or of the left. In his two succeeding books, Ideas Are Weapons (1939) and Ideas for the Ice Age (1941), he continued to preach the importance of right thinking as a weapon against the foreboding future. The philosophertheologian Reinhold Niebuhr was similarly concerned with the importance of right thinking as a guide to effective

action. In his The Children of Light and the Children of Darkness (1944), he carried over into popular form his attack upon the sentimental conception that there is no such thing; he had first presented this attack in his The Nature and Destiny of Man (1941 and 1943), one of the important philosophical works of the century.

Sharing with both Niebuhr and Lerner many common ideas about the necessary basis for a good future, Stuart Chase, Lewis Mumford and Louis Adamic attacked more particularized aspects of the problem. In such books as The Culture of Cities (1938) and The Condition of Man (1944), Mumford pointed out the way in which the development of technology had affected the destiny of man and looked forward to an age of more humane men in a more humanely technological society. Louis Adamic, himself a naturalized American, attempted in his books (From Many Lands, 1940; Two-Way Passage, 1943; A Nation of Nations, 1945) to make America aware of the troubles of immigrants and minorities in the U.S. and to induce a more actively liberal attitude. He also published an interesting book about Yugoslavia, My Native Land (1943), and a provocative account of the relations between Churchill and Roosevelt, Dinner at the White House (1946).

In addition to a number of books about the tragedy of waste in an economy that could make ample provision for all (Idle Men, Idle Money, 1940; Democracy Under Pressure, 1945), Stuart Chase wrote what was the most popular introduction to the new science of semantics (q.v.) which intended to make people more aware of the merely verbal source of many social misunderstandings. This book, The Tyranny of Words (1938), was followed by a number of similarly oriented books such as S. I. Hayakawa's Language in Action (1941), an accurate and brilliantly written primer for the uninitiated, and Wendell Johnson's excellent People in Quandaries (1946). Thurman Arnold's earlier The Folklore of Capitalism (1937), a satirical account of many less rational beliefs under capitalism, anticipated much of what the later semanticists had to say.

Closely allied to the semanticists in their belief that modern society required more rational conduct and a more honest recognition of frequent irrationality, were such anthropologists as Margaret Meade and Ruth Benedict and such psychiatrists as Karl Menninger and Karen Horney. Ruth Benedict's The Chrysanthemum and the Sword (1946) was a notable attempt to apply this kind of reasonableness to Japanese society, while Margaret Meade's Keep Your Powder Dry (1942) applied a similarly objective rationality to civilization in the U.S. In a series of books that included Man Against Himself (1938) and Love Against Hate (1942) by Karl Menninger and The Neurotic Personality of Our Time (1937) and Our Inner Conflicts (1945) by Karen Horney, publicists for psychoanalysis tried to show harried modern man how he could better order and sublimate his inherent irrationality.

After starting her career with an amusing attack on the English. With Malice Toward Some (1938), Margaret Halsey published two of the decade's most popular and effective indirect pleas for tolerance: Some of My Best Friends Are Soldiers (1943) and Color Blind (1946). Particularly in the latter book, she made a winning plea for more general acceptance of Negroes as complete equals. On a somewhat less popular level, St. Clair Drake and Horace Cayton's Black Metropolis (1945), a study of the Negro section of Chicago, pointed to the great need for accepting Negroes as first-class citizens, as did Arna Bontemps and Jack Conroy's They Seek a City (1945), a study of

Negro migration in the U.S. Similarly, Robert S. Lynd and Helen Merrell Lynd's *Middletown in Transition* (1937) indicated the need for greater tolerance in the U.S.

The most effective conservative social critic of the decade was undoubtedly Walter Lippmann. In his carefully reasoned *The Good Society* (1937) and his popular and logical *U.S. Foreign Policy* (1943), he outlined the possible structure of an effective internal and external policy for the *U.S.*

* * *

No Account of the decade 1937-46 would be complete without mention of such thoroughly unclassifiable writers as Henry Miller, Gertrude Stein and James Thurber. Thurber was most generally known as a humourist, and he was certainly a delight for tired minds. But he was serious as well, and there was much in Let Your Mind Alone (1937), My World-And Welcome to It (1942) and his collection, A Thurber Carnival (1945) that was vital criticism of the frequently neurotic American way. The Selected Writings of Gertrude Stein (1946) and Wars I Have Seen (1945) revealed that Miss Stein should be taken seriously too. Because of the excessive difficulty involved in reading much that she wrote, she had foo frequently been dismissed as an eccentric. In similar fashion, Henry Miller had been too frequently dismissed as a pornographer. In attempting to move toward a more notably happy decade, readers might make greater mistakes than reading the eloquent savagery of Miller's two best books, The Cosmological Eye (1939) and Sunday After the War (1944). Amsterdam

The capital of the Netherlands showed a certain economic recovery in the year 1937, as the result of which the

general unemployment figure fell to 25.7%. The steadily increasing international trend toward autarchy, particularly in Germany, continued to exercise an untavourable influence on the economic situation of the city. In the year 1938 especially it became clear that a world-wide conflict was inevitable, and consciousness of this set its seal on many aspects of Amsterdam's life. The following spring, the city was full of newly mobilized Dutch troops, yet for a year the terrors of war remained outside its walls. On May 10, 1940, German aircraft bombed Schiphol airport; five days later German troops occupied the city. The measures taken against the Jewish inhabitants (10% in total) roused the resistance of the population. Feb. 25. 1941, the day on which tens of thousands went on strike as a protest against the persecution of the Jews, was a milestone in the history of the city. The year 1944 was marked by the so-called "Mad Tuesday" (Sept. 5) on which the retreat of the German troops and the panic flight of the quislings seemed to be the prelude to speedy liberation. Hope of this, however, was destroyed after the failure of Arnhem (Sept. 17-28). Schiphol airport was totally devastated and the seaport badly damaged. Stoppage of rail and tramway traffic, the cutting off of gas and electricity supplies followed quickly. The already scanty rations continued to be cut; thus a state of emergency arose; thousands of people (both young and old) died of cold and starvation. The following year started with a continued increase of the distress; more and more areas around the town were flooded; the situation became precarious.

The liberation of the city on May 5, 1945, saved tens of thousands from famine; a week before, Allied food supplies dropped by air had already met the very worst needs. But still the weight of 44,000 of the city's inhabitants was 25% below normal; it was recorded that 25,000 citizens were suffering from hunger-oedema. In the second half of the year restoration of what was most necessary took place. As soon as the harbour and airport were opened, supply of gas and electric service was resumed. The year 1946 saw the first transatlantic air traffic. Municipal elections in July showed a left-wing majority (Labour 31%, communists 32%). In all branches of civic life, reconstruction and recovery were forging ahead.

Anaemia

The stimulus to knowledge of the blood given by the work of G. R. Minot and W. P. Murphy in 1926 (on the action of liver in producing remissions in pernicious anaemia), carried over into the 1937–46 decade. Efforts were made to discover the nature of the active material in liver extract, and experiments suggested that it was a biuretnegative peptide. The chemical formula was not developed.

Pernicious Anaemia.—Many studies were made on the nature of the process in the stomach which developed the material that causes maturation of the red blood cells. Experiments suggested that a substance, probably the enzyme haemopoietin, secreted by the body of the human stomach (or the pyloric region in the hog) reacted with a constituent of the food and produced a material which was stored in the liver. This substance ("liver extract").

on reaching the bone marrow, enabled immature red blood cells (megaloblasts) to develop into mature cells. A defect in available liver extract caused the development of large red cell (macrocyte) anaemias, such as are found in pernicious anaemia, tropical macrocytic anaemia, achrestic anaemia, sprue, pellagra, some patients with gastric carcinoma and certain nutritional anaemias. Removal of the stomach in man and animals gave different results in the hands of various operators, most frequently being followed by an anaemia with small red blood cells, although a few instances of macrocyte or large red cell anaemia were reported. The atrophic appearance of the stomach in pernicious anaemia so that the tissues appeared as if dead, improved during a remission, although the ability to secrete haemopoietin was not recovered.

. Bone Marrow Puncture.—During the decade 1937–46. bone marrow puncture, both for diagnostic purposes as well as for transfusion of blood and fluids in anaemia. became a routine procedure. The red cells are formed in the bone marrow.

Colon bacilli were found throughout the gastro-intestinal tract, from the stomach to the colon, in patients with pernicious anaemia in relapse. The neurological symptoms in this disease, present in some form in from 70% to 90% of the patients, were favourably influenced or their progress was checked by the use of liver preparations, desiccated stomach, vitamin B_1 , other vitamins, yeast and folic acid.

Potency of Liver Extract.-Numerous attempts were made to find a suitable method of determining the potency of liver extract, since chemical means were not available. The effect of liver was studied on the size and development of red blood cells in the immature opossum, in rat embryos, chick embryos, guinea pigs, in isolated bone marrow preparations, in dogs, in animals with their stomachs removed, or with bile fistulas, on special diets, or poisoned with various chemical substances. None of these came into common use during the decade. The use of untreated people with pernicious anaemia remained the only suitable test for the power of liver extract and the measurement of the increase in the number and percentage of reticulocytes-immature red cells-and the rate of increase in the number of red blood cells was adopted as the standard. A quantitative relationship between the initial red blood cell count at the beginning of intramuscular liver therapy in pernicious anaemia and the maximum percentage of reticulocytes which appeared in the blood stream during the following two weeks was expressed by a mathematical formula. The familial incidence of pernicious anaemia was reported as from 7.9% to 18.7% in different surveys.

The treatment of pernicious anaemia became standardized, and the intramuscular injection of the remedy was found to be the most economically effective. Folic acid, thiamine and similar substances (vitamin B_c, vitamin M, norite eluate factor) were found to be effective in the treatment of macrocyte anaemias.

Macrocyte Anaemias.—Many types of macrocyte anaemia were studied. A nutritional type was described in men and animals on deficient diets, in pregnancy, after gastrointestinal operations (entero-enterostomy), in liver disease, in achrestic anaemia, in some tropical diseases, in malaria, in children, idiopathic steatorrhoea, in carcinoma of the stomach and in other conditions. Some of these responded to the folic acid group of substances, whether concentrate (yeast, liver, spinach) or the synthetic form. As with

pernicious anaemia, a transitory swelling of the feet and legs was noted during the early remission in macrocyte anaemias.

Iron Deficiency Anaemias.—Iron deficiency anaemias in animals were studied extensively, and observations on man were recorded. Ferrous iron is more readily absorbed in man than ferric iron or organic combinations, but this varies in animals. Animals are favourably influenced by copper and cobalt. Radioactive iron was used to "tag" haemoglobin, and thus observers could follow its formation and metabolism in the body. Tagged iron was found in red blood corpuscles of anaemic dogs four to eight hours after ingestion. Iron phytate was less readily absorbed than ferrous sulphate. While radioactive iron was absorbed only in traces in nonanaemic dogs, it was taken up abundantly when there was iron deficiency. The absorption appeared to depend more on the reserve iron store than on the degree of anaemia. About 70% of iron injected intramuscularly was used for regeneration of haemoglobin, the red colouring matter of the blood. When given orally, multiple small doses of iron were more efficient than single large doses in causing regeneration of haemoglobin.

A number of surveys of groups in different parts of the world were reported, with special reference to the incidence of anaemia. In communities in England, the United States, India, Africa, and in the Shoshone Indians, studies showed the prevalence of iron deficiency anaemia, especially where there were dietary inadequacies.

Iron deficiency anaemia was found in 9.0% to 72% of pregnant women. In breast-fed infants it was less common (26%) than in bottle-fed ones (35%). In adults it varied from 3.6% to 30.0% and in children from 1.5% to 85.0%. In 2,205 rural school children in Florida, 42.3% had haemoglobin values in the range of 3.6 to 11.4 grams per 100 c.c. secondary to dietary, especially iron, deficiency. Two-thirds of the natives of northwest India showed lack of haemoglobin (hypochromia) and iron deficiency, associated with an inadequate iron intake. In Manchester, England, anaemia was found in 58% of 201 children (10 weeks to 14 years).

Significance of the Rh Factor.—Of outstanding interest was the discovery that a group of substances, the "Rh factor," was present in the red blood corpuscles of about 85% of the population. This substance was antigenic when injected into a person who did not possess it (Rh negative). The substance thus developed in the blood of Rh-negative people agglutinated red blood cells of Rh-positive people. An Rh-positive foetus in an Rh-negative mother caused her to develop antibodies which produced erythroblastic anaemia in subsequent Rh-positive children. An Rh-negative person who had developed Rh antibodies (from an Rh-positive blood transfusion, or from bearing an Rh-positive child from an Rh-positive husband) could not receive a transfusion of Rh-positive blood, as a severe haemolytic reaction, destroying red blood cells, and often fatal, resulted. Many subgroups or subtypes and correlated factors were discovered. The Rh factor was found to be inherited as a dominant character, through six allelic genes,-Rho Rh1 Rh2 Rh', rh and Rh". The incidence in England and in the U.S. was similar, but Rh-negative people were 21 times less frequent among the Chinese, and erythroblastosis was rare. The subtypes were postulated as factors in haemolytic blood transfusions and in erythroblastosis foetalis. The latter condition caused 2.2% of foetal deaths, and 2.8% of

those in infants. Haemorrhagic disease of the newborn was fatal in 2.1% of a group of infants. In one study, 21 cases of haemolytic disease in the newborn, 19 of the mothers showed anti-Rh agglutinins in their blood and in the breast milk in 7 of 10 patients examined. A preponderance of the fathers of children with haemolytic anaemia, as in the case of erythroblastosis foetalis, were homozygous Rh-positive. Erythroblastosis was almost twice as common among children of Rh-negative women who had been sensitized previously by transfusion, than in those not so affected. Haemolytic anaemia, secondary to Rh-antibodies, was the initial cause of erythroblastosis foetalis, and by damage to the tissue of the liver, gave rise to many of the complex manifestations of the disease. The titer of anti-Rh substance was highest in mother and child, 8 to 20 days after delivery. Transfusions of Rh-negative blood through the umbilical cord in a prematurely delivered Rhpositive infant exposed to anti-Rh substance, was followed by recovery. Erythroblastosis foetalis was not always present in infants when Rh-antibodies were present in the maternal circulation. Erythroblastosis was reported in children of Rh-positive mothers, suggesting other possible

Haemolytic Anaemia.—Many cases of haemolytic types of anaemia were reported. A haemolysin in the blood was postulated, sensitizing the cells so that they were destroyed by the spleen or reticulo-endothelial cells elsewhere. Haemolytic reactions developed in some patients with cold agglutinins. In Marchiafava-Micheli (paroxysmal nocturnal haemoglobinuria) anaemia, visible haemolysis developed in clotted blood after six hours at 37°C. Following the general introduction of the sulfonamide compounds (sulfanilamide, sulfathiazole, sulfadiazine, sulfapyridine) into medicine, many instances of haemolytic anaemia were reported. In this condition, pigment metabolism and renal failure resembled that in blackwater fever, haemolysis after incompatible transfusions, haemolytic jaundice and haemolysis from various drugs. A haemolytic anaemia followed the feeding of choline to dogs, with rapid recovery after cessation of the administration of the drug. The anaemia was hyperchromic, responding to anti-pernicious anaemia treatment. The haemolytic reactions resulting from isoimmunization following repeated transfusions of homologous blood developed according to a mechanism similar to that affecting the erythroblastic foetus and endangered the life of transfused anaemic mothers. Several factors relating diet and haemolytic anaemia were noted. The anaemia produced by para-amino-benzene was prevented by a high protein diet. Increased destruction of red blood cells followed diets rich in fat. Rats on a high fat diet developed a severe anaemia after trinitrotoluene poisoning, but were protected by a high protein or carbohydrate intake.

A number of studies were made, especially on animals, using various diets and medicines to learn the best treatment for iron deficiency anaemias, and accumulate knowledge about haemoglobin regeneration. Cobalt and copper appeared to enhance the utilization in some animals, but not in others. The iron of egg yolk, spinach and blood was not easily digested, and under some circumstances (achlorhydria, achylia) only a very little was used. Careful studies were made of the amino acids essential for haemoglobin regeneration in animals. Molasses (concentrated syrup from cane sugar) was found to be an easily available source of iron. Growing rats developed anaemia when placed on a milk diet which was not relieved by the addition of lactalbumin, corn, wheat gluten or iron, but was helped by copper, casein and similar substances.

Pyridoxine deficient diets produced a microcytic hyperregenerative anaemia in swine, corrected by pyridoxine administration. There was no increase in haemolysis in pyridoxine deficiency anaemia in swine, but ferraemia and haemosiderosis were the result of nonutilization and decreased excretion of absorbed iron. Vitamin B_{θ} , a constituent of liver extract, cured anaemia of certain types in chicks. An erythropoietic substance developed in the serum of rabbits rendered anaemic by bleeding. Diets low in protein, pantothenic acid, casein hydrolysate, zein, pyridoxine or B-complex were reported as causes of anaemia.

Sickle Cell Anaemia.—Many new investigations were made of patients with sickle cell anaemia. The abdominal crises were found to be associated with packing of the small capillaries with red blood cells, stagnation, haemolysis and anoxaemia. The flooding of the liver with products of haemolysis probably accounted for the higher rate of cholelithiasis in these patients than normal. In Central America sicklaemia appeared in 9.6% of the individuals examined in the Canal Zone; 9.6% among the British West Indians and 11.2% of the Panamanians. While the sickling phenomenon appeared in 5%—6% of American Negroes, it appeared in 15.5% of the fit and 25% of sick natives of West Africa.

Sickle red blood cells were about twice as permeable to potassium ions than normal, and the sedimentation rate was slower than normal. A characteristic habitus of the patients was described. High concentrations of inspired oxygen depressed erythrocytogenesis but there was no consistent detectable change in haemolysis. Sicklaemia was described in white persons and in one white youth it simulated an acute surgical condition. Severe joint pains, without residual damage characterized some cases.

The increase in the haematocril reading above 20 mm. per hour following treatment of sickle cell anaemic blood with carbon dioxide was of diagnostic value. (Normal blood, less than 20 mm.)

Preservation of Blood for Transfusion.-The problem of preservation of blood for transfusion ("blood banks") received much attention. In stored blood, the leukocytes and platelets disintegrated rapidly, and there was a loss in the prothrombin content. For anaemia, red blood cells stored in the cold up to 18 days were but little inferior to fresh blood, and such cells could be detected in the circulation for from 70 to 90 days. Placental and cadaver blood was also used successfully for blood transfusion. Reactions from stored blood were not more numerous than from fresh blood. Blood corpuscles injected intraperitoneally, enter the general circulation, and therefore must be of a compatible type in order to be therapeutically valuable. "Universal blood" (group O cells) was made safe for transfusions by the addition of group specific substances A and B. Group O cells, suspended in pooled plasma, reduced the number of reactions.

There was a transitory increase in serum bilirubin after transfusion of stored blood not noted when fresh blood was used. Blood transfusions were given directly into the marrow and the cells entered the circulation just as in transfusions given intravenously.

The use of concentrated red blood cell suspensions for transfusion in anaemia came into general use. A rise of approximately 1 gram of haemoglobin per 100 c.c. followed the infusion of each 300 c.c. of erythrocyte suspension, and the risk of a reaction from transfused isoagglutinins was minimized.

Donors of blood for transfusion regenerated their blood

eight times more rapidly when they took iron medication than when the regeneration was allowed to continue spontaneously. The iron of white bread was found to be available for haemoglobin regeneration, but not that of brown (wheat meal) bread. However, after the introduction of national wheat meal flour in England, the average haemoglobin levels of school children and pregnant women were higher than in preceding years. In the treatment of dogs with anaemia of chronic haemorrhage, it was found that human liver was 20% to 60% more effective than animal liver. Liver and liver extract had value as accessories in haemoglobin regeneration after venesection in dogs.

In acute haemorrhage in man there were no symptoms until the patient sat up or stood up. Syncopal attacks were accompanied by bradycardia. Fainting was the result of neurogenic vasodilation in the muscles.

The anaemia of scurvy was found to be caused by generalized depression of erythropoiesis rather than a failure of maturation from a specific lack of vitamin C. In hiatal hernia, 66% of those affected showed some degree of hypochromic anaemia of haemorrhage, occasionally, however, of the pernicious anaemia type. Dimorphic anaemia, a combination of deficiency of iron with a nutritional macrocytic anaemia, was described in Uganda. A new type of severe hereditary anaemia of boys, transmitted through unaffected females, was also described.

Although most of the patients with anaemia fell into one of two groups, those responding to iron and those responding to liver, folic acid or desiccated stomach, there were some who did not improve. These were grouped under the term "refractory anaemias," and blood transfusion was the only treatment of symptomatic value. Aplastic types of anaemia were described after the ingestion of aspirin, after antisyphilitic treatment and after sulfathiazole. Some patients with aplastic types of peripheral blood showed bone marrow quite rich in cellular elements, whereas others showed hypoplasia or aplasia of the marrow cells. No adequate explanation of this paradoxical observation was formulated.

The concept of a "terraine morbide" in the development of anaemia was supported by numerous observations—the pernicious anaemia familial type, congenital haemolytic anaemias, development of anaemias of various types in different members of the same family, the varying reactions of different people to the same stimulus, as benzene, radioactive substances, drugs, or dietary deficiencies. The patients who succumbed to the different elements in their environment attracted the attention of observers, but inadequate studies were made of those who, in similar circumstances, did not develop anaemia.

Spies, "The Present Status of Folic Acid," Blood 1:271-306 (July 1946). (R. Is.)

Anaesthesiology

"Anaesthesiology" is a word coined about 1940 to include the practices involved in preparing patients for anaesthesia and their care during and after receiving any anaesthetic. During the decade 1937-46, anaesthesiology

reached full stature as a specialty in medicine, and organizations of anaesthesiologists were perfected.

New Anaesthetic Substances.-Many new ethers were prepared and used experimentally. Among these were cyclopropyl methyl, cyclopropyl ethyl, n-methyl propyl, ethyl n-propyl, propenyl ethyl, propethylene, cyprome, cypreth, cyprethylene and cyclopropyl vinyl ethers. Some of these were given clinical trial, but none had yet established a firm position in clinical use by the end of the decade. Trichlorethylene (trilene), which had been used in inhalation anaesthesia, was found less toxic to the heart than chloroform but not always capable of producing complete muscular relaxation. It was used in obstetrics. Investigators found that toxic products formed by interaction of this product with soda lime in a closed circuit might produce palsies of some of the cranial nerves. This agent might also break down into toxic products under the influence of heat, such as the electric cautery. Used in safe concentration for anaesthesia for short periods, the hazard of toxicity was found minimal.

New Techniques.—Continuous caudal anaesthesia was developed in 1942. Breakage of needles caused trouble at first, but the use of an indwelling catheter which was suggested later reduced this difficulty. Proper selection of cases, and care and skill in carrying out the procedure determined the success or failure of this method of anaesthesia. Its greatest use was in obstetric anaesthesia, but it was found to be useful also in certain surgical cases and for therapeutic uses.

Continuous spinal anaesthesia was first used in 1939. This outstanding contribution made it possible to utilize the safer agents for spinal anaesthesia and still assure the surgeon of sufficiently long-lasting effects. At first a malleable needle was left in the subarachnoid space, and intermittent injections of the anaesthetic agent were made. In 1944, the introduction of a catheter instead of the needle simplified the technique and eliminated the need for a specially designed mattress which had been necessary when a needle was used.

Equipment.—New devices for carbon dioxide absorption, for intravenous administration of drugs, for inhalation anaesthesia as well as for special methods were developed.

The Horton intercoupler was introduced for the purpose of reducing static electricity which might cause explosions in the gas machine.

The intratracheal method of anaesthesia became increasingly useful. Development of plastic type of tubes did not meet with full success. Attachments for, and modification of, tubes added to the applicability of this valuable method of administration.

Intravenous anaesthesia, particularly with pentothal sodium, was used extensively by civilian and military anaesthetists. Pentothal may be used for persons in shock if the dose employed is small in contrast to the dose for a robust patient. Evipal soluble, eunarcon, avertin fluid, as well as other drugs were used for intravenous anaesthesia in a fewer number of patients than pentothal. Later, procaine was given intravenously to produce anaesthesia.

Anaesthetic Adjuvants.—Curare, which is not an anaesthetic, was first used in 1942 to increase relaxation of the skeletal muscles in patients under general anaesthesia. Its initial success continued. It was given intravenously with the inhalation anaesthetics cyclopropane, nitrous oxide, ethylene and ether. With ether the dose must be decreased. It also was used in pentothal sodium intravenous anaesthesia, but a mixture of too much of the drugs in a syringe

or needle forms a precipitate. Respiratory depression or alrest occurs from overdose of curare or from too rapid injection. Drugs with curarelike action were studied. Among these were salts of erythroidine, nicotine, thiamin, magnesium, quinine, quinine ethochloride, other quinine derivatives and ammonium salts. Artificial respiration until respiratory depression is overcome and prostigmine are the antidotes to over-effects of curare.

Bronchoscopy was developed into an important adjunct to successful anaesthesia. Operative and postoperative tracheobronchial aspiration reduced the incidence of serious pulmonary complications.

Helium was used with anaesthetics in situations in which respiration may have been obstructed, when it was necessary to anaesthetize a patient during an asthmatic attack or when an asthmatic attack developed while the patient was being anaesthetized.

Intra-osseous (intramedullar) administration of shortacting barbiturates as well as blood and blood substitutes was introduced for use in special, difficult situations.

Hypnotism found a limited usefulness in obstetrics, therapeutics and surgery.

Oxygen for postanaesthetic use proved valuable, and many devices were made for its administration.

Penicillin was added to anaesthetic solutions in an attempt to increase the usefulness of local anaesthesia, especially in infected regions which previously had been avoided. Studies were made which showed that procaine did not interfere with the activity of penicillin.

Sulfonamides were studied in relation to local anaesthetic agents, inhalation agents and the barbiturates. Procaine was found to have antisulfonamide action. Acetylation of the amino group of p-aminobenzoic acid leads to a 10,000-fold decrease in the antisulfonamide activity of procaine. Studies of anaesthetic agents used for patients treated with sulfonamides indicated that inhalation anaesthesia, being the most controllable type of administration. was preferred to less controllable methods. Sulfanilamide in large doses was found to affect the toxicity of pentothal sodium in rats. No ill-effects, however, were demonstrated among patients heavily medicated with sulfonamides and anaesthetized with pentothal sodium, and no synergism between the two drugs was seen. It was found, too, that sulfonamides did not increase the risk of shock to the animal and in some instances seemed to be beneficial.

The relation of vitamins to anaesthesia was studied as well as the effect of the vitamin state in the preanaesthetic and postanaesthetic periods. Vitamin C deficiency was found to increase anaesthetic induction time and recovery time, and vitamin B_2 was found necessary to adequate functioning of the cell respiratory mechanism.

Analgesics and Sedatives.—Barbiturates continued to appear in increasing numbers during the decade. Vinbarbital sodium was found to be an effective hypnotic and sedative when used in a wide variety of disease states. Seconal was used with good effect for a variety of conditions.

Demerol (1-methyl 4-phenyl piperidine 4-carboxylic acid ethyl ester hydrochloride) was synthesized in 1939. It is an analgesic with atropinelike properties and morphinelike effect on the central nervous system. It has spasmolytic and sedative effects. It was used for preanaesthetic medication and extensively in obstetrics.

Improvements in Anaesthetics.—Cyclopropane continued to be used increasingly during the ten years. Devices to increase its safety as well as special precautions against explosions and improvements in carbon dioxide absorbers decreased the disadvantages of this valuable agent.

Diethyl ether continued to hold its dominant place

Demonstration by U.S. medical officer of proper method of administering spinal anaesthesia, at the Titon General hospital in Fort Dix, N.J. Continuous spinal anaesthesia, first introduced in 1939, was one of the most important new anaesthetic techniques made available to surgeons during the decade 1937–46

among the inhalation anaesthetics as it completed its first 100 years as a surgical anaesthetic.

Divinyl ether also continued to give satisfaction for certain operations. Its usefulness, however, was limited by the ill-effects which occur after prolonged administration.

Nitrous oxide, which in 1942 had been used as a surgical anaesthetic for 100 years, continued to be used extensively, but the anaesthetist became increasingly aware of the need for precautions against suboxygenation with the subsequent danger of cerebral damage. Its greatest use was for induction of anaesthesia and in combination with other agents.

The explosion hazard in anaesthesia was studied, and safety measures were recommended and accepted. With this acceptance came a renewed confidence in cyclopropane and ethylene; previously their use had been limited or discontinued because of the danger of explosion.

The use of local anaesthesia was limited largely by the ability of the anaesthetist and the time required for its application. The intravenous route of administration of morphine increased its usefulness.

Refrigeration as a form of anaesthesia of the extremities was developed, and though limited to a relatively small group of cases, was found of value in prevention of shock, especially in diabetic surgery. Skin grafts were removed painlessly after refrigeration of the donor area.

Shock, its relation to anaesthesia and its treatment when it developed during anaesthesia, was also studied. Supportive measures were used increasingly and with successful results. Treatment of shock in persons wounded in battle decreased the casualties. Blood transfusion, plasma transfusion and blood substitutes were used more as a preventive therapy, thus reducing the incidence of operative shock.

Geriatrics, developed into a specialty, was of interest to anaesthetists who had followed already established principles in applying knowledge of anaesthesia to the increasing number of patients who require surgery in the later years of life. (See also Surgery.)

BIBLIOGRAPHY.—Several new journals began publication during the decade. Volume I of Anesthesia Abstracts appeared in 1937, Revista argentina de anestesia y analgesia in 1939 and in July 1940 Anesthesiology was first published. In 1945, Journal of the American Association of Nurse Anesthetists appeared; it had been issued previously as a bulletin. These journals increased to nine the total number of journals dealing with anaesthesia.

Ancient Monuments, British

The decade 1937-46 in Britain saw an increasing interest in the care of ancient monuments, and an extension of the activities of those bodies, public and private, concerned with their recording, preservation and ownership. The royal commission on historical monuments (England) was appointed in 1908 "to make an inventory of the ancient and historical monuments and constructions connected with or illustrative of the contemporary culture, civilization and conditions of life of the people of England . . . and to specify those which seem most worthy of preservation." The commission proceeded county by county, and published 19 fully documented and sumptu ously illustrated inventories covering nine counties. The royal commission on ancient monuments (Scotland) and the royal commission on ancient and historic monuments for Wales and Monmouthshire were appointed in the same year and produced similar inventories; Northern Ireland had no commission, but the Ancient Monuments Advisory council for Northern Ireland, established in 1934 with the support of the finance ministry and subscribers, issued a single volume on the same lines as the commission inventories,

Early in the air attack on Britain during World War II, urgent need was felt for as complete a record as could be made of outstanding buildings, both ecclesiastical and domestic, of all periods, lest any of them should be destroyed unrecorded. Following a meeting convened by the Royal Institute of British Architects in 1941, the National Buildings record was established, with the support of the treasury, and financial assistance from the Pilgrim and Leverhulme trusts, and the Rockefeller foundation. Working in close collaboration with the royal commissions, this central depository had by 1946 built up a collection of some 300,000 photographs and architectural drawings. The archaeology department of the ordnance survey was concerned with marking finds, ancient sites and monuments on the O.S. maps, and with collecting records, air-photographs, etc., relating to them. The ordnance survey from time to time published period maps.

These bodies, however, were concerned solely with the recording of ancient monuments and had no power to ensure their preservation. These powers were exercised by the ministry of works under the Ancient Monuments acts of 1913 and 1931. Upwards of 350 ancient camps, barrows, castles, abbeys, etc., were in the guardianship of the state under these acts in 1946. The excellent preservation that had been carried out by the ancient monuments department of the ministry of works was widely known and appreciated. Temporary protection was afforded to a far greater number of monuments by a system of scheduling, for no scheduled monuments might be materially altered without the knowledge of the department. Over 5,000 monuments were provisionally protected in this way. Furthermore, the act of 1931 empowered the department to undertake excavations on threatened sites not under its guardianship. Good use was made of this during the war and the period of rearmament that preceded it, when the building of factories and airfields for military purposes entailed the destruction by service departments of many lesser monuments such as earthworks and prehistoric burial mounds.

As a result of this emergency excavation, carried out by experts often under trying conditions, more than 100 burial mounds and many other important sites were scientifically examined before destruction, and no major monument was lost without adequate record. The department was also called upon, with the ready collaboration of the ministry of home security, the Royal Institute of British Architects and of many local architects, to render first aid to many historic buildings seriously damaged by German air raids, at a time when no other body was equipped to deal with the emergency. By prompt action such as shoring or protection from exposure, many ancient buildings were saved from collapse.

The Society of Antiquaries, founded in 1707, had always been vigilant in the care of ancient monuments, and had taken a prominent part in the excavation of such historic sites as the prehistoric hill-fort of Maiden castle, Dorchester, the Roman fort at Richborough, and the Roman cities of Verulamium (near St. Albans) and Camulodunum (Colchester). During the war, the need was felt for a national body to focus archaeological opinion in view of the tasks imposed by war damage to such ancient sites as London, Exeter and Canterbury, and the changes inevitable in the period of development and reconstruction after the war. The Council for British Archaeology was formed in 1943 to meet this need. On it were represented national and local archaeological societies, learned soci-

eties, universities and museums. It was concerned with the co-ordination of research and the expression of informed archaeological opinion on such subjects as aerial survey and the threat to ancient monuments.

Excavations had been carried out at Canterbury and Exeter by local committees in advance of rebuilding, and in 1946 the Roman and Mediaeval London Excavation council was set up under the presidency of the lord mayor to explore the 100 ac. that lay waste within the walls of London before they were again built over. Apart from national bodies, numerous county archaeological societies had ancient monuments committees which were vigilant in their own districts, and many published lists of scheduled monuments in their areas. The National Trust (q.v.) owned more than 100 ancient monuments, in particular inhabited houses, which lay outside the scope of the ministry of works. It acquired the famous prehistoric site of Avebury.

The care of cathedrals and churches was primarily the concern of the diocesan authorities, but a movement that had gained impetus and usefulness was the formation of societies of friends of cathedrals like Canterbury, York and Dunblane, who collected funds for the repair and adornment of the fabric. Similar bodies were formed for the care of other places, e.g., Abingdon, where the friends (1946) had undertaken the preservation of the remains of Abingdon abbey.

Anderson, Clinton Presba

Anderson (1895-), U.S. government official, was born Oct. 23, 1895, in Centerville, S.D. After attending Dakota Wesleyan university, Mitchell, S.D., and the University of Michigan, Ann Arbor, Mich., he went to New Mexico and worked in journalism and later as an insurance salesman in Albuquerque. In 1935, Anderson was placed in charge of the state's relief administration, and he was chairman of the New Mexico Unemployment Compensation commission (1936-38). In 1940, he was elected on the Democratic ticket to the U.S. house of representatives and was twice re-elected. Anderson voted against the Roosevelt administration on several domestic issues but approved generally the government's foreign policy. On May 23, 1945, President Harry S. Truman appointed Anderson secretary of agriculture, and the following month the War Food administration was transferred to Anderson's control.

At the height of the world famine in early 1946, he was opposed to U.S. food rationing and declared that such measures would prove impractical. Anderson also was at odds with Chester Bowles and Paul Porter on removal of price controls. Congress solved this dispute in Anderson's favour by stipulating in the new price control act of July 26, 1946, that the secretary should not be subject "to the direction or control of any other appointive officer

or agency in the executive branch of the government." This gave Anderson authority to act independently of other government agencies.

Anderson, Sir John

Sir John Anderson (1882-), British statesman, was born July 8, 1882, in Scotland; educated at Edinburgh and Leipzig universities, he entered the British colonial office at the age of 23. After World War I, he was dispatched by the government as its official "trouble shooter" to Ireland and Bengal; in both areas he employed strong measures to cope with "unrest." He was permanent under-secretary of state for the home office, 1922-32, and governor of Bengal, 1932-37. After his return to England, he was elected to commons, 1938. That same year he was made lord privy seal and minister of civilian defense, and was appointed home secretary and minister of home security in 1939.

Sir John was lord president of the council, 1940-43. After the death of Sir Kingsley Wood, Sir John was named chancellor of the exchequer, Sept. 24, 1943. Sir John lost his seat in the cabinet in the general elections in the summer of 1945. However, he was made chairman of the British Advisory Commission on Atomic Energy and accompanied Prime Minister Clement Attlee to Washington in Nov. 1945 for the Truman-Attlee-King joint talks on atomic energy. He expressed the view that it would be "many years" before atomic energy could compete with existing sources of industrial power. Earlier he had warned that the advent of atomic energy made a complete readjustment of international relations and the forming of a new social order mandatory.

Anderson, Sir Kenneth Arthur Noel

Sir Kenneth Anderson (1891–), British army officer, was born Dec. 25, 1891. He was educated at the Royal Military college at Sandhurst and entered the army in 1911 as a second lieutenant in the Seaforth Highlanders. Wounded in World War I, he was awarded the military cross. After the war, he advanced through the grades and was made a major general in 1940. In 1942, Gen. Dwight Eisenhower chose Gen. Anderson as one of his three task-force commanders in French North Africa. Raised to the rank of acting lieutenant general, Anderson led the British 1st army in the combined Allied campaign in North Africa, Nov. 1942 to May 1943. In the early part of that campaign, he attempted a quick dash to seize Tunis and Bizerte before the arrival of axis reinforcements in those strategic ports. However, German panzers and new axis troops, ferried by air transport from Sicily, balked this drive. In July 1943, he was given the permanent rank of lieutenant general. A month later, he was knighted in recognition of his services in the war. On Feb. 13, 1944, he was named head of the eastern command in Great Britain.

Andrews, Elmer Frank

Andrews (1890-), U.S. government official, engineer, industrial adviser and labour consultant, was born Nov. 22, 1890, in New York city. He studied at Rensselaer Polytechnic institute, graduating as a civil engineer in 1915. He supervised construction of sugar warehouses and railways in Cuba, was associated for a brief period with the compensation insurance rating board of New York state and served as a lieutenant in the U.S. air force in World War I. After the war, he worked with several railways and the Queensboro Chamber of Commerce, where he was in charge of highway and bridge

construction.

Andrews, who became industrial commissioner of the state of New York in 1933, also served as adviser to the National Labor Relations board in mining districts and in 1934 was made head of the U.S. observers at the International Labour organization conference in Geneva. In 1938 he was named by President Franklin D. Roosevelt as administrator of the Fair Labor Standards act. He left this post the following year and subsequently became a consultant on labour relations.

Andrews, Frank Maxwell

Andrews (1884-1943), U.S. army officer, was born Feb. 3, 1884, in Nashville, Tenn. He was graduated from West Point in 1906, became a cavalry lieutenant and was promoted through the grades to colonel in 1935. Gen. Andrews saw service in the Philippines, 1906-07, and in Hawaii, 1911-13. During World War I he served as a major in the signal corps and from 1920 to 1923 served with the army of occupation in Germany. He was appointed temporary major general of the air corps in 1935 and commanded G.H.Q. air force from 1936 to 1939. While in the latter post, Andrews piloted an army air corps amphibian bomber 1,425 mi. from San Juan, Puerto Rico, to Langley field, Va., setting a new world's distance and straight-line record for amphibian planes. In Sept. 1941 he was promoted to the rank of lieutenant general and was appointed head of the Caribbean defense command and the Panama canal department. On Nov. 4, 1942, Gen. Andrews was given command of all U.S. forces operating with the British in the middle east zone. On Feb. 5, 1943, he was named to succeed Gen. Eisenhower as commander of all U.S. forces in the European theatre of operations. He was killed when a U.S. bomber in which he was a passenger crashed in Iceland, May 3, 1943.

Anglican Communion

The Anglican communion is that body of Christians, in the British empire and elsewhere, who are in full communion with the archbishop of Canterbury. At the end of the decade 1937–46, it contained 320 dioceses and perhaps 9,000,000 communicants.

Although World War II postponed the seventh Lambeth conference from 1940 to 1948, a focused impression of the Anglican communion may be gained from the wider setting of the third World Missionary conference at Madras, India, in Dec. 1938, where all the leading churches (except Rome) of some 70 different countries were represented. Four features prominent at Madras were developed by the ensuing six years of war: (1) the growth of indigenous leadership: 145 delegates from the younger (missionary) churches formed more than half the membership at Madras, a significant contrast with Edinburgh, Scotland (1910); (2) the rise of church consciousness: the church itself, rather than any missionary agency within it, was recognized as the ordained instrument of evangelism, although the value of missionary societies to engender and express evangelistic activity was acknowledged; (3) the progress of oecumenical co-operation, hailed by Archbishop William Temple as "the great new fact of our era"; (4) the discovery of the extreme importance of the Anglican communion in contemporary Christendom; this had already transpired at the two great oecumenical conferences of 1937, at Oxford ("Church, Community and State") and Edinburgh ("Faith and Order"), which culminated the following year in the formation of the World Council of

churches. English, thenceforth, became the common language of occumenical Christianity.

United States.—The Protestant Episcopal Church (q.v.) of the United States of America came to realize its membership in the Anglican communion more fully. Thus, during the war, gifts from the Episcopal Church of America to Anglican missionary societies totalled \$570,000; exchange visits of English and U.S. bishops were arranged; and joint spheres of work were replanned in the West Indies, such as the appointment in 1942 of a U.S. bishop to the English diocese of Nassau, and the agreement to transfer the Central American republics from the English diocese of British Honduras to the American diocese of the Panama Canal Zone.

These years were for the Episcopal Church "an encouraging decade." Though its communicant membership did not number more than 1,500,000 of the United States's 132,000,000, its comprehensive character had a wide appeal. When immigration ceased with the war, communicants increased at double the rate of the population.

Three movements, manifest throughout the Anglican communion, assumed a characteristically active form in the United States. The liturgical movement, born of a deepened church consciousness, focused attention on tradition and ritual. The orthodox movement back to biblical theology flamed, as in England, into an urge for evangelism. The oecumenical movement gave rise to a commission on approaches to unity, with the Presbyterian Church specially in mind.

British Commonwealth.—The Church of England in Canada exchanged, in 1939, the hardships of a nine years' drought for the even graver dislocations of war, which claimed as service chaplains no fewer than one-eighth of the 1,630 clergy on its active list. Although missionary work among Indians suffered thereby, and church returns of every kind showed a decline, the three movements, so notable in the United States, were pre-eminently active in Canada. In 1945 a committee was appointed to consider prayer book revision. The general synod, in 1946, unanimously commended for study proposals for reunion between the Church of England in Canada and the United Church of Canada (formed in 1925).

The church in Australia and Tasmania accounted the years 1937–46 some of the most formative in its history. The people were made serious by the threat of invasion. Church life was quickened by the advent of U.S. chaplains and exchange visits between religious leaders of the two countries. The eyes of fighting men were opened to the triumphs of the gospel in the Pacific islands: more particularly in the dependency of New Guinea, where eight missionaries were killed at their posts by the Japanese.

There arose an all-embracing urge for evangelism. "Religion and Life" weeks were organized on a united front, and important steps were taken to claim for the church the leadership of men and women returning from war service. "Bush" church agencies reinforced their activities. A newly formed National Missionary council planned, with a similar body in New Zealand, a postwar conference to strengthen and co-ordinate missionary work in the Pacific.

The province of New Zealand (which included the two missionary dioceses of Melanesia and Polynesia) exhibited the same trends and joined in the formation of a national council of churches, which organized in 1945 a conference on "Christian social order."

The province of South Africa, confronted with widespread materialism and an acute "colour" problem, became conscious of a new spirit in the union, that began to regard its pattern of black and white no longer as antagonistic but co-operative. Evangelistic campaigns organized by the Christian council of South Africa, the splendid conduct of African troops and the discovery of the intellectual and artistic capacity of native children in missionary schools all contributed towards the new outlook.

The missionary churches of Africa presented a marked contrast between mass movements towards Christianity by pagan peoples in central and east Africa, and "holding the fort" in Moslem areas in the north and west. African Christians proved themselves the best missionaries to their fellows, as also leaders among African troops. The future seemed largely to depend on the use made by the churches of those returning from the development and discipline of war service, and their resettlement in the backward life of their home community. A disturbing feature was the extraordinary growth of native Christian "mush100m" sects. In South Africa alone, these increased from 75 in 1918 to nearly 800 in 1945. The situation called for the authority of a strong, co-ordinated church, giving urgency to proposals for the formation of new Anglican provinces both of west and east Africa, and also to the movement towards that larger unity already taking shape in south India, which was watched with eager eyes by missionary churches all over the world.

The younger missionary churches, cut off from western assistance, or in axis occupation, emerged from the war with a new-gained maturity that promised impressive advance and increased influence, despite many local disasters, more particularly in Manchuria. Indigenous church leadership developed, both with the rise of national consciousness and through the self-dependence imposed on native clergy and congregations by war conditions. Church consciousness developed through the intermixture of peoples and their common sufferings and experiences. To the pressure of heathenism, more particularly in Moslem countries, was now added this larger church consciousness which overrode accidental loyalties to western denominationalism. The war revealed the younger churches to servicemen of the older churches, and to the pagan peoples around them, as well as to themselves.

The church of India, Burma and Ceylon markedly demonstrated these features. The magnificent way in which the Church of England had transformed its missionary stations into an autonomous and independent church went far to remove the danger of the expulsion of British missionaries when India should assume self-government. Church consciousness was thus enabled to keep pace with national consciousness and exert a Christian influence on Indian politics; this was exemplified by the inclusion of a Syrian Christian, Dr. John Matthai, as minister of finance in Lord Archibald Wavell's provisional government in 1946. The strength of the church was shown by the consistency of Indian Christians in war service; they returned with a wider outlook and disciplined character that qualified them for Christian leadership of a high order. The scheme for a united church of south India (which included four Anglican dioceses) progressed towards fulfilment despite the organized opposition of extremists in England, and was accepted in 1946 by all three of the negotiating church bodies. As over 95% of those affected by the proposal would be Indians, the question for the Anglican communion as a whole was its attitude towards the united church during an interim period of 30 years, before full communion would be achieved. This would be the concern of the Lambeth conference of 1948.

The Burmese diocese of Rangoon afforded a war record

typical of most missionary churches under the heel of the Japanese, and more particularly of its neighbouring diocese of Singapore, where the whole Christian community combined to maintain the life of the church when its heroic bishop was interned and tortured. Three native priests who had kept the church alive despite persecution, threats and torture were appointed archdeacons with the return of peace. Buddhists no longer regarded Christianity as an alien system but as exhibiting an enviable quality of life among themselves. British and U.S. forces made it their business to assist in refitting churches after their desecration by Japanese.

Far East.—The Holy Catholic Church in China (Chung Hua Sheng Kung Hui) suffered inevitable devastation and dislocation from eight years of Japanese invasion (1937–45). Its vitality, however, was apparent in national leadership, missionary activity and the organization of relief services. Although Chinese Christians (of all denominations) numbered only 7 in every 1,000 of the population, yet in a Who's Who, published during the war, 1 name in 6 was that of a Christian, and 1 in 3 had received a Christian education.

Although 10 of China's 13 dioceses were occupied by the invader, the church still maintained its missionary work in the Shensi diocese among the border peoples of Mongolia, Turkestan and Tibet. Although congregations were scattered, their members became missionaries in other regions. Moreover, the leading part played by the church in educational and Red Cross work was itself evangelistic. The Church of England accounted it a privilege to hand to Bishop T. K. Shen, in June 1946, the first instalment of a promised gift of \$402,000.

The Japan Holy Catholic Church (Nippon Seikokwai) celebrated in 1937 its jubilee as an independent church, though the Church of England still provided seven of its ten bishops and about half its income. In 1940, rising national feeling dictated the advisability of the withdrawal of foreign missionaries and support. This, however, did not prevent the Japanese government from recognizing only two Christian bodies, the Roman Catholic Church and a "Japan Christian Church" comprising all other denominations. About one-third of the Nippon Seikokwai joined, in 1942, this united Protestant church, and the three seceding bishops consecrated seven more. Two-thirds of the church stood firm despite threats, imprisonment and the loss of corporate existence.

In 1946 an Anglican commission visited Japan. It found the church bankrupt and with most of its property destroyed by bombing, but conscious of a strengthened faith. The visit provided the occasion for an approach towards the healing of the division, and for an appeal to the older churches to rally to a great opportunity for advance. The extent of the opportunity could be gauged by the general testimony of internees and prisoners of war in the far east, that they experienced humane treatment wherever the Japanese in authority were Christians. (See also Church of England.)

Angling

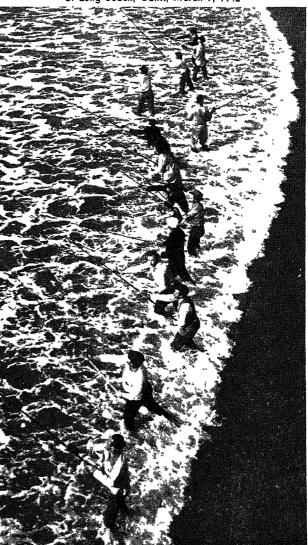

Perhaps the best-way to evaluate the increase in popularity of angling during the decade 1937–46 was on the basis of angling licence sales in the United States. They showed a gradual increase from 1937 through 1945 from 6,197,240 to 8,280,232. (Sales on the basis of the fiscal year ending June 30.) Figures for the years 1938 to 1944 were

as follows: 1938, 6,643,195; 1939, 6,890,130, 1940, 7,858,275; 1941, 8,004,034; 1942, 8,423,218; 1943, 8,028,674; 1944, 7,846,168.

Licence sales alone, however, were only an indication of the general trend in sport fishing. In many states, resident women were still not required to have licences; all states allowed children to fish without them, and nowhere was a licence required for salt-water fishing. The actual number of anglers, then, remained much larger than the number of licences held.

In salt-water sport fishing, perhaps the most significant development during the period was the formation of the International Game Fish association in June 1939 and its rapid growth after that date. It was established to serve the interests of anglers and to add to the general knowledge concerning fish. It concerned itself with anything relating to ocean fish and fishing, both from the standpoint of the sportsman and the scientist, and served as a clearinghouse for the exchange of information between anglers and ichthyologists. Its headquarters were established in the American Museum of Natural History, in New York city, with which it became officially connected Despite the difficulties of expansion during the war.

Records compiled by the National Association of Angling and Casting clubs.

the I.G.F.A. by the end of the decade had 59 member organizations in 36 sections of the world, including the United States, Africa, Australia, Bahamas Islands, Bermuda, British Isles, Canada, Canal Zone, Costa Rica, Cuba, Fiji Islands, France, Hawaiian Islands, Mexico (northern), Mexico (southern), New Zealand, Newfoundland, Philippine Islands, Puerto Rico, Netherlands West Indies, South America, Belgium, Malaya, Windward Islands, Tahiti, Marianas Islands, Tobago and Trinidad.

The I.G.F.A. was the only recognized body maintaining records in salt-water angling. There was still no comparable organization in fresh-water angling, although the National Association of Angling and Casting clubs continued to hold an annual tournament and to be responsible for records in the tournament casting field-records compiled by Field & Stream magazine.

The N.A.A.C.C. was founded in 1906 and enjoyed a continuous growth-a growth which continued during the decade despite the interruption of World War II. In addition to holding its annual tournament, in which teams and individuals from member clubs in all sections of the United States participated, the organization was responsible for many of the improvements made in fishing tackle. It led the way in standardizing line sizes, leader sizes and hooks and made progress toward the acceptance of a recognized fishing terminology.

A number of improvements in fishing tackle were made during the period. The one which had the greatest effect on angling generally was the development of nylon

by the E. I. du Pont de Nemours and company in 1939. Nylon was placed on the market both in monofilament form, used chiefly for leaders, and in braided lines. This new product had a strong impact on the fishing tackle business. Previously, there had been no serious competitor for braided silk lines or for silkworm gut leaders. Nylon was both. In addition, since it did not rot in salt water, it was a serious competitor to linen lines.

The I.G.F.A. in 1946 still was evaluating nylon and attempting to arrive at a fair basis for comparison between fish caught on it and linen. From the time of Izaak Walton, silkworm gut had had no serious competitor as a material for leaders. Because of war requirements, nylon was withdrawn from commercial sale, but was made available again in Oct.

Another improvement in fishing tackle was the perfection of a process to impregnate bamboo rods with bakelite, thereby adding considerably to the strength and durability of the ma-

terial. This process was worked out by the Charles F. Orvis company of Manchester, Vt., in 1941. A war development of great benefit to fly fishermen was the silicon resin waterproofing materials. These compounds were adapted to dry-fly oil and line dressing and were far superior to anything previously known.

The general trend in fishing tackle during the decade was toward the use of lighter, more sporting equipment.

Anglo-Egyptian Sudan

A condominium under the joint sovereignty of Great Britain and Egypt, south of Egypt, the Anglo-Egyptian Sudan has an area 967,500 sq.mi.; pop. (est. 1942) 6,591,000. Chief towns: Khartoum (cap., pop. 1944, including Khartoum North) (76,724); Omdurman (est. 1944) (104,513);

Wad Medani (est. 1942) (41,000); El Obeid (est. 1942) (39,887); Port Sudan (est. 1943) (35,617); Kassala (est. 1941) (30,026). Languages: Arabic, English, various Nilotic and Negro tribal languages and dialects. Religion: Mohammedan; south Sudan is 20% Christian, 80% pagan.

Governors-General during the decade 1937–46: Lt. Colonel Sir Stewart Symes (Jan. 1934–Oct. 15, 1940); Lt. General Sir Hubert Huddleston (after Oct. 16, 1940).

* * *

THE YEAR 1937 was the first year after the reaffirmation by Great Britain and Egypt of the treaty of 1899 by which they agreed to administer the country jointly. The Gezira cotton scheme, one of the most modern large-scale cooperative enterprises in the world, had been in operation for 12 years and was building up to the pre-eminent position which it occupied in the country's economy at the outbreak of World War II, when it was contributing 25% of the whole revenue of the country. One of the difficulties with which the department of agriculture was faced was the ancient system of dividing up crops between a number of co-owners, which had resulted in extreme fragmentation of land. In the years 1937-46, the institution of private co-operative and government pump schemes continued, and its further development was limited only by the Nile Waters agreement which determined the respective shares of Sudan and Egypt in the waters of the Nile.

The Gezira irrigation scheme, started in 1925 as an answer to the problem of levelling an adverse balance of trade and to guarantee a grain supply in case of famine, more than justified during the war the bold planning and foresight of the government and was a solid bastion against famine panic. In 1942, after three poor rains and two years of war, the price for grain in Khartoum rose no higher than £E7 (\$29.67) per short ton, whereas before the start of the scheme in bad years grain had reached the very high price of £E17 (\$71.61) (the average exchange rate for the years 1939-43 being 1£E=\$4.13). Cotton remained far and away the Sudan's best suited crop, and even the primitive natives and pastoral Arabs of the Nuba mountains were persuaded to grow it. Their crops alone for the years 1938-40 were worth more than £E100,000 each year.

From the very first, education had been regarded as of paramount importance. An appeal to the British public two years after Kitchener's defeat of the Mahdi in 1899 led to the foundation of the Gordon Memorial college described by Lord Salisbury as "a great effort to break down the obstacles of race, to establish the bond of intellectual sympathy and to further the pursuit of human culture," and it was no new departure from precedent when in 1937 the government approved new proposals involving capital expenditure of nearly £E500,000 and an increase of annual expenditure of £E150,000 as a result of the findings of the De La Warr commission on education. It was then planned to start post-secondary courses so as to develop eventually a college of university status while the output of teachers for both boys' and girls' schools was to be doubled. World War II delayed the fulfilment of these schemes. Gordon college was taken over by the army and also the first of the new secondary schools when completed at Wadi Seidna. Sudanese staffs were unable to go on post-graduate courses overseas. The schools of law had opened in 1936; two years later the schools of veterinary and agriculture were opened; in 1939 the schools of science and engineering; in 1940 the school of arts. An innovation in 1942 was the opening of two junior secondary schools, while the success of the elementary teachers' training college led to a revision of the intermediate school curriculum. In 1944, the army evacuated Gordon college, and its status was raised to that of a university college.

During the years 1937–46 much progress was seen in overcoming resistance to female education, and in 1945 there were 65 government schools attended by 6,495 pupils in addition to one intermediate school and a teachers' training college. A number of mission and community schools also operated for Sudanese girls. The main difficulty to overcome was the custom of early marriage, which limited a girl's teaching life.

A notable feature of the work of the forestry department was the introduction of the mesquite tree from America. This proved a valuable anti-erosive agent in semi-desert conditions and also provided highly nutritive fodder for cattle and in case of need an edible flour for human beings. The war and consequent demand for timber made feasible the cutting of the tropical softwood podocarpus, which abounded in the mountains on the Sudan's southern border with Uganda, and transporting it to markets in the north.

The Sudan medical service had a widespread and comprehensive organization. In the years 1937–46, the emphasis was changing from curative to preventive treatment. There was hospital accommodation for over 7,000 people at a time and in 1943 100,000 in-patients were treated, while there were nearly 8,000,000 out-patient attendances. The infant mortality rate for Khartoum was, in 1943, 72 to 86 per 1,000, which compared favourably with other tropical cities. There was extensive vaccination against smallpox, and a large-scale campaign against sleeping sickness was successful although a large organization had still to be maintained in the affected area.

Railway traffic had steadily increased because of the effects of the war and general increased prosperity. In 1943, the total tonnage of goods handled was 1,316,398 while the number of passengers carried in the same year was 1,675,304. Permanent all-weather roads were constructed in the south in the years 1937–46 linking the country with Uganda and the Congo. Air transport was beginning to play an increasingly important part in the country's communications, and its development was facilitated by Khartoum's position at the intersection of the main air routes from South Africa to Egypt and from West Africa to Asia.

The main factor contributing to the new wealth of the country was the increase in trade, both internal and external. The veterinary service concentrated on developing an export market for Sudan cattle and sheep by building up a reservoir of good quality stock. They were at last winning in the long fight to obtain the stockbreeders' cooperation in the war on rinderpest and pleuro-pneumonia, but it was more difficult to make them see the need for selective breeding to obviate over-stocking of grazing areas and progressive deterioration of stock and soil. During World War II the country exported cheap meat on a scale which in 1937 would have been thought far beyond its capacity.

The history of the Ethiopian campaign made it quite clear that if the Anglo-Egyptian Sudan had fallen in 1941, Egypt would have been untenable to the British because the supply line to middle east via the Red sea and across Africa from Takoradi to Khartoum would have been severed. But when war was declared by Italy the Sudanese defense force succeeded in bluffing the Italians that they were far stronger than they really were. All forms of munitions were produced in the workshop of the Sudan

railways and public works department while the people of the Sudan gave over £E200,000 to various allied war funds and invested £E747,000 in war savings.

In 1946 the Umma (Sudanese Nationalist, anti-Egyptian, led by Sir Abdel Rahman el Mahdi Pasha) party sent two representatives to Cairo to the Anglo-Egyptian treaty revision conference. Much rioting in Khartoum took place as a result of rumours and statement of Sidky Pasha that the Sudan would be embodied under the Egyptian crown (see Egypt). Gordon college was shut. Three thousand Umma party followers demonstrated in Khartoum in October and presented a petition to the governor calling for independence.

Severe flooding of areas of country around Khartoum and Omdurman occurred in Sept. 1946, when the Blue Nile reached a height of 55.7 ft.—the highest recorded since 1917—and burst its banks.

Anthropology

Few decades since the establishment of anthropology witnessed more ferment, more change, more re-examination of accepted points of view and more exploration of new avenues of study than the period 1937–46. Positions that had previously been only enunciated grew into full vigour. Problems that had been the subject of speculation took on specific statement and were attacked in programs of field research oriented methodologically along new lines. It would be distorting the historical picture and doing an injustice to earlier students to say that anthropology was a different discipline at the end of the decade than at the beginning, yet it remained nonetheless true that it was by no means the same science as in the years preceding 1937.

It was not strange that most of the new currents that characterized anthropology during the period were initiated and developed in the United States and England. Europe knew only two years of peace, and after 1939 European anthropologists had little opportunity for the field study that is the essence of anthropological research. In Germany, during the entire period, nazi theories of race and culture made conventional anthropology difficult, if not impossible to carry on. Except for those who were politically quiescent and restricted their research to the most remote and exotic problems, the only anthropology Germany knew was the prostituted rassenkunde that bolstered the claims of the "master race." That the blight did not later spread into the occupied countries was due to the heroism of those who refused intellectually to surrender to their conquerors. Many paid with their lives, others with their liberty, or sought exile. It was remarkable that the lines of achievement reached at the outset of World War II could be held, and the very substantial studies that began to reach the outer world from France, Belgium, the Netherlands and Denmark when the war ended could be published.

In the U.S., however, half the decade was little touched by war—officially, not at all. When war did strike, though it took many anthropologists from their customary posts, enough remained in the universities and museums not only to carry on a considerable proportion of their usual activities, but also to extend the boundaries of concept and available data along the lines laid down during previous years. In England, also, while most of the available anthropologists went into war service, the exigencies of the colonial service encouraged some study of native peoples, and stressed application of its findings to the problems of native rule.

The gains made by anthropology during this war decade in countries where it had existed previously either in rudimentary form, or as the avocation of amateurs, were particularly striking. Anthropology in Latin America, especially Mexico, Brazil, Peru, Haiti, Colombia and Venezuela, attained a status and commanded trained personnel as never before. In India and China, also, despite the travail these countries experienced, new university posts, new research institutes, and study along new lines characterized their anthropological decade.

Several reasons accounted for the flowering of anthropological science during the period. In all countries, an increasing tendency toward professionalization of the science was manifest. Anthropologists who received training leading to the doctorate steadily increased, both in absolute number and in proportion to those who, in earlier

Native of New Guinea helping U.S. signal corps linesmen string telephone and electric wire during the U.S. campaign in New Guinea. Anthropologists were of prime importance in making such co-operation possible by contributing to the armed forces their knowledge of the languages and customs of native peoples all over the world

times, would have claimed recognition because of the circumstance of their work as colonial officials, or as missionaries, or as travellers. Merely to gather information became insufficient; questions came to be raised more and more insistently about the reasons for gathering data, the nature of the problem being studied, the theoretical frame of reference that guided research.

A second reason for the growth of anthropology was the developing realization that, in a world society, the science that looks at man in the round, so to speak, must have an important contribution in establishing and perpetuating a world order. The cultural relativism taught by anthropology, that stressed the dignity and worth of all ways of life, however they might differ, came increasingly to be recognized as an important and perhaps indispensable philosophical basis for a society that was to include the most diverse types of traditions. At the same time, the work of anthropology in combating racism, another consequence of its stress on the unity of mankind, brought about added recognition of the contribution this science could make to solving the problems of human living.

Finally, anthropologists tended to turn more and more to the study of problems closer at hand than the remote subjects of their earlier interest. Physical anthropologists intensified their investigations of the growth and development of children, or of the formation of population types. Cultural anthropologists began to apply their methods to the study of literate peoples as well as illiterate—"primitive"—folk, to analyze the results of culture-contact as well as to seek out presumably uncontaminated "savage" cultures, to investigate the manner in which different cultures shape the individuality of those who live in accordance with them. Linguists applied their techniques to written as well as unwritten languages, and began to use their techniques in teaching students how to master new and strange tongues. Folklorists came to recognize the vital quality of the songs and stories and other living word-of-mouth literary forms, as well as the survivals of past belief with which they had previously been almost exclusively occupied.

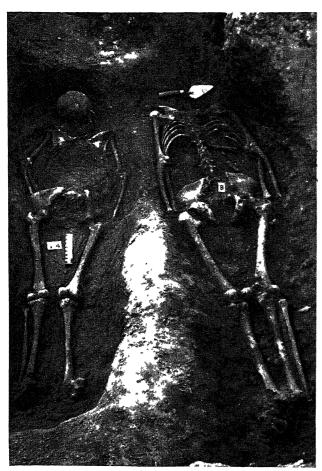

We may now consider in turn the changes that took place in each of the principal divisions of anthropology during this decade, which witnessed the 100th anniversary of the founding of two of its oldest societies, the Royal Anthropological institute of London and the American Ethnological society of New York. Not only the development of methods and theories during the ten years must be indicated, but also some of the more significant new data that anthropologists made available.

Prehistoric Archaeology.—The story of the evolution of human physical forms underwent drastic revision as a result of new finds. The system of classification of prehistoric old world cultures was critically re-examined, and new terminologies and points of view were developed; the problem of the coming of man to the Americas was restated, and the succession of cultures in many parts of the new world during the period before European contact was established was clarified.

At the beginning of the decade there was general agreement concerning the sequence of forms that marked the course of human evolution. First came the Java ape man (Pithecanthropus erectus), then the Peking form (Sinanthropus pekinensis), discovered in 1929, and then Piltdown man (Eoanthropus dawsoni), though there had always been some debate regarding the nature of these remains. "Human" types followed-Heidelberg man, Neanderthal man and finally Cro-Magnon, the earliest form of Homo sapiens, and the first representative of modern man on earth. Certain African finds, such as the Rhodesian skull and the South African Australopithecus, were believed to be shoots off the main evolutionary tree, though the former was admitted to be of Neanderthal affiliation. All these forms were held to belong to different species, each of which had replaced the preceding one, and no crossing between them was postulated.

New finds, especially from the far east, threw open all these assumptions to re-examination. F. Weidenreich, who most exhaustively analyzed the data, new and old, advanced hypotheses some of which would be debated for years. His conclusions concerning the significance of these finds for problems of the evolution of the human form and the differentiation of races were made available in 1946 to the lay reader in a short summary published under the title Apes, Giants and Men. Definitive statements of his conclusions for the scientific world were contained in his monographs, The Skull of Sinanthropus Pekinensis (1943), and Giant Early Man from Java and China (1945).

The new finds were made principally by G. H. R. von Koenigswald. His discoveries began in 1935 with the find-

Skeletal remains of prehistoric California man unearthed by University of California scientists near Lodi, in the Sacramento valley, during Nov. 1937

ing, in a Hong Kong apothecary shop, of a great tooth that, as he believed, came from a giant ape, which he named Gigantopithecus blacki. In 1939, however, when excavating at Trinil, the site where Pithecanthropus had been recovered many years before, he discovered what was first regarded as a large male skull of this species. In 1941, however, in central Java he came upon one and perhaps two Pithecanthropus-like mandibles, so large that it had to be assumed that they derived from a different form. In the meantime, Von Koenigswald, in 1937, had acquired a second great tooth from another Chinese apothecary shop, and two years later a third. On study, it became apparent that these teeth had not belonged to a giant ape, but to a giant man, which Weidenreich maintained should have been called Gigantanthropus rather than Gigantopithecus. This led to a reconsideration of the evolutionary position of the Java finds, with the result that the jawbones were recognized as another giant early type and named Meganthropus palaeojavanicus, while the new large Pithecanthropus skull was called Pithecanthropus robustus.

Other discoveries of importance, made elsewhere, were analyzed during these years. Work at the site where Sinanthropus pekinensis had been recovered progressed until halted by the invasion of China by Japan, with the result that a large series of remains, from a considerable number of individuals came to light. Work on the significant Mt. Carmel finds went forward, analysis proving that this was a transitional form between Neanderthal man and Homo sapiens. The discovery in England of the Swanscombe re-

mains, lodged in middle Pleistocene deposits, was followed by the announcement of the findings of a commission of the British Association for the Advancement of Science that left no doubt of its significance as showing that a type morphologically closer to modern man than Neanderthal had existed in this early period. Further finds in South Africa by R. Broom brought this area prominently into the picture as a region where significant steps in the evolution of man occurred.

At the end of the decade, then, the picture of the development of man differed in several important respects from the conception of it held at the beginning. Geographical perspective was re-established, the preponderant role assigned Europe in the process of human evolution being corrected by a realization of the importance of forms that had developed in the far east and Africa. A high degree of variability for certain prehistoric types was proved, as well as the fact that forms manifesting differing degrees of morphological development had coexisted from earliest times. This led to hypotheses that were the subject of considerable controversy-that all so-called "human" and "protohuman" types must belong to a single species, mutually fertile as they are today; that present-day races must be thought of as far older in point of origin than had been assumed; and that the human animal represents racial mixture to a degree, and over a period of time hitherto unrealized. Most dramatic was the question raised whether earliest man may not have been a giant form, the human adventure thus having been marked by diminution in the size of successive types, rather than each having been larger than its predecessor.

The study of the prehistoric development of culture was marked by a re-examination of pre-existing approaches to the data. Numerous discussions of this problem were published in the Proceedings of the Prehistoric Society of England, where Dorothy Garrod and others pressed arguments for the reclassification of prehistoric cultures on the basis of industry types rather than in terms of a world-wide application of a presumed succession of lithic forms derived from the study of European sites. A similar position was taken by H. L. Movius, Jr., in whose monograph "Early Man and Pleistocene Stratigraphy in Southern and Eastern Asia" (in the Papers of the Peabody museum, 1944) the applicability of conventional designations was rejected in favour of the two generic types "hand-ax cultures" and "chopping-tool cultures." Similarly, G. E. Daniels, in a short but significant work entitled The Three Ages (1943), presented the case against the use of the time-honoured classification of prehistoric cultures into stone, bronze and iron ages. He pointed out that these were applicable only to Scandinavian prehistory, from which they had been derived, and that designations such as "core" and "flake" industries were far preferable to "old stone age," "middle stone age," much like O. Menghin, the Austrian prehistorian, who earlier suggested the term Protolithic for lower and middle Palaeolithic, and Miolithic for upper Palaeolithic and Mesolithic "ages."

Of greater significance than these terminological disputes was the development by V. Gordon Childe of a functional approach to archaeology, in his works Man Makes Himself (1937) and What Happened in History (1942). His use of outmoded designations such as "savagery" and "barbarism" for prehistoric civilizations, however, represented a distinct regression in terminology. He envisaged the development of human civilization as having been made possible by three great revolutions. The first was the Neolithic Revolution, which changed palaeolithic hunting, foodgathering society into stable groupings through the estab-

lishment of an assured and abundant food supply as the result of the domestication of animals and plants. Then, with the discovery of metalworking, wheeled transport and irrigation, came the Urban Revolution that placed man in cities and was marked by the rise of foreign trade, industrial specialization, social stratification and slavery and dynasties. Finally came the Industrial Revolution, with the power machine and the techniques of science. Whether the decade 1937–46 witnessed the fourth, or Atomic Revolution, only time could tell.

In new world archaeology, where problems differed from those of the Euro-Asiatic-African area, the decade witnessed a heightened intensity of field investigation and a sharpening of techniques. The summary of the evidence for the antiquity of man in America by F. H. H. Roberts, Jr., "The New World Paleo-Indian" (Ann. Report, Smithsonian Institution, 1944, pp. 403-434), which presented the evidence thus far available on the antiquity of man in America, indicated that while man may have migrated to the new world from Asia toward the end of the Pleistocene, many of the animals killed by the early peoples constituted what were usually considered Pleistocene forms that "seem to have survived through the transition to Recent times and then to have become extinct rather suddenly." As to the controversy concerning the time man reached the new world, greater hospitality was given to the idea that longer periods than the conventional 10,000 years accepted earlier may have elapsed since his advent.

Techniques of archaeological study were marked by continued refinement of the dendrochronological methods of dating by the scrutiny of tree-ring patterns, with the extension of this method from southwest sites to those of the Mississippi valley. Methods of analysis were improved, also, when midwest archaeologists, following W. C. McKern, agreed on a terminology that named a local find as a focus, related to an aspect of a wider but still restricted form of a culture called a phase, of a pattern that, either by itself or in combination with another, characterized an entire area. This terminology was effectively employed by F. C. Cole and T. Duell, in their work Rediscovering Illinois (1937) which offered an excellent summary of Mississippi valley archaeology in the light of modern methods of study. For the rest, great archaeological activity in Mexico, Central and South America, carried on through the co-operative efforts of institutions of higher learning and governmental organizations of all countries concerned, marked the period. (See also Archaeology.)

Physical Anthropology.—The trend was steadily toward the study of the more dynamic aspects of human biology as against the description and classification of racial and subracial groupings, though much work of the older kind continued to appear in the journals, and the study of constitutional and somatic types gave a new impetus to the classificatory approach. C. Coon's Races of Europe (1939) was the most ambitious attempt made during the decade at racial classification. It was accorded a mixed reception, as was another study by E. A. Hooton in criminal anthropology which, in a more modern application of the Lombrosian approach, concluded that persons of certain physical types tended to commit particular types of crimes. Continuing and refining the earlier work of the German student, E. Kretschmer, W. H. Sheldon, in his volumes The Varieties of Human Physique (1940) and The Varieties of Human Temperament (1942), devised a series of "somatotypes" which were held to reflect temperamental and psychological predispositions as well as to define constitutional types. Sheldon's methods, no less than his conclusions, raised considerable controversy, but work along

the lines he laid down continued to be actively prosecuted. The disastrous consequences of the use of the concept of race for political ends, as manifest in the racist dogmas of the nazis, had many repercussions among physical anthropologists. Statements were adopted by several anthropological societies protesting against the misuse of scientific findings concerning human physical type, and considerable sentiment was manifest at the 1938 Copenhagen meeting of the International Anthropological congress against the racist sentiments voiced by E. Fischer, the fuehrer of the German delegation. G. M. Morant's Races of Central Europe (1939) outstandingly demonstrated how inept was the idea that the populations of this area could be classified as belonging to different races. A pamphlet by R. Benedict and G. Weltfish, The Races of Man (1943), explaining the facts about race, though banned by the U.S. army and refused circulation by United service organizations (U.S.O.), sold over 1,000,000 copies. A more extended analysis by M. F. Ashley Montagu, Man's Most Dangerous Myth: the Fallacy of Race, appeared in its second revised edition (1945). In England, We Europeans (1936), by J. S. Huxley and A. C. Haddon had attracted wide attention, while G. Dahlberg's Race, Reason and Rubbish, a Primer of Race Biology (1942), contributed a telling Scandinavian

contribution to anti-racism. Controversy over the 1910 findings of F. Boas regarding the change in bodily form of immigrants continued. The weight of accumulating evidence, however, supported the fundamental thesis of this scholar, whose death was the heaviest single loss to all branches of anthropology in a decade marked by the death of an unusually large number of outstanding anthropologists. A critique of Boas' statistical approach by R. A. Fisher and H. Grey (1937) drew a reply from Boas defending his methods. In studies by H. L. Shapiro on Hawaiians, published in the volume Migration and Environment (1939) and by M. S. Goldstein on Mexicans, Demographic and Bodily Changes in Descendants of Mexican Immigrants (1943), these independent investigators obtained results that were essentially the same as those of Boas' earlier research. It seemed likely that the controversy over heredity versus environment would be resolved by the recognition of the fact that organisms do not inherit traits, but limits within which they may vary in accordance with their individual life experience. (See also Psychology.)

Interest in the problems of human growth and development, carried on earlier by such students as R. Martin in Germany and F. Boas and T. W. Todd in the United States, was intensified. Added to this, however, was concern with the terminal periods of the human life-span, as was shown by the institution of a Journal of Gerontology. Studies of the problems of child growth were aided and stimulated by the work of W. M. Krogman, The Growth of Man (Tabulae Biologicae, vol. xx, 1941), which contained tables that incorporated the results of all studies in any aspect of child growth. The study of human heredity continued, in the main, to rest in the hands of animal geneticists and others whose point of view did not take into adequate account the importance of nonbiological tradition in influencing physical type through selection in mating, and in shaping other aspects of population formation.

Linguistics.—The field of anthropological linguistics was marked by continued refinement of method. The earlier controversy over the validity of the phonemic approach to linguistic analysis died down with the recognition of the values in this attack, so that linguists were freed to use this

tool rather than required to devote effort in justifying it. The decade's greatest gains were in the study of American Indian and African languages, to the latter of which much effort was given by English and continental students, though research in Australian and Oceanic tongues also went forward. As the decade ended, work had begun under the auspices of the International African institute looking toward publication of a handbook of African languages, while in the U.S. the International Journal of American Linguistics, founded by F. Boas, reappeared under the editorship of C. Voegelin, after a lapse of a number of years, and a new map of American Indian language families was issued by the American Ethnological society.

The knowledge of the anthropological linguists was made great use of during World War II, particularly in the United States. In the army area and language training program, and in army and navy military government schools, where men were taught the ways of life of peoples with whom they would be required to deal, the intensive language training program in a few months equipped them to speak and understand languages that were earlier held to take years to learn. This was accomplished principally by employing native speakers of these tongues, in a way analogous to that in which anthropological linguists used informants in the field study of unwritten languages. Because it differed radically from earlier methods of language teaching, because of the success that attended its use, and because of its implications for revision of peacetime language study, this method was much discussed. Its influence, however, was increasingly felt in university language instruction. The recognition of the values inherent in the study of pidgin and creole dialects was a significant aspect of the general movement which tended to broaden the focus of interest of all language students beyond their concern with Indo-European tongues. A notable effort in this direction was the publication by the Modern Language association of the Grammar of Melanesian Pidgin (1943) by R. A. Hall, Jr.

Cultural Anthropology.—Newer developments in this field must be considered against a background of the continued prosecution of research and publication along lines that were well established at the beginning of the decade. In all the countries of western Europe, notable achievements of this kind were recorded, especially in France, Belgium, the Netherlands and Denmark, where work went on despite the German occupation.

One of the most important single events was the holding of the second International Anthropological congress in Aug. 1938, in Copenhagen, that brought together a larger and more representative gathering of anthropologists from all over the world than probably any previous meeting of its kind. Of great significance, also, was the opening of the Musée de l'Homme in Paris, under the directorship of Professor Paul Rivet. Consolidating the headquarters of all the French anthropological societies, and comprising the centre of all anthropological teaching in Paris, its influence was quickly felt. In England, the research program of the International African institute went steadily forward, and the position of anthropology in English universities was strengthened with the appointment of A. R. Radcliffe-Brown to a chair of anthropology in Oxford, giving that institution its first professor in the discipline since the death of E. B. Tylor many years before. English anthropological journals continued to issue during the entire period of the war.

A number of new journals appeared during the decade,

and most older continental publications carried on despite the war. Ethnos, G. K. Lindblom, editor, published in Sweden, and the various museum publications of that country, came out regularly; in Denmark, a new society devoted to arctic research, with a journal entitled Acta Arctica Scandinavica, was begun despite the occupation. During this time, also, the centenary of the founding of the department of ethnography at the National Museum of Denmark was celebrated by initiating a new series of reports. Older Russian periodicals continued to appear, and a new one, entitled Kratkie Soobcheniia, was first issued in 1945. An enlargement of the program of the Institut Français d'Afrique Noire, and the regular issuance of its periodical, Notes Africaines, was achieved after the liberation of Dakar. Formation of a Palestine Institute for Folklore and Ethnology was announced, and its journal, Edoth. completed its first volume. In China, most of the anthropologists, like other scholars, moved west before the Japanese invasion. One result of this migration was the strengthening of the West China Frontier Research insti-

In the new world, the Southwestern Journal of Anthropology, under the editorship of L. Spier, began publication in 1943. Acta Americana, the organ of the Inter-American Society of Anthropology and Geography, edited by R. Beals, appeared shortly after the formation of that organization in 1942. In 1945 the first number of Afroamerica. the journal of the new International Institute of Afro-American Studies in Mexico City, was issued. The South African journal, Bantu Studies, broadened its field of interest as indicated in its new title, African Studies. A development also to be noted in this area was the founding of an anthropological research centre in northern Rhodesia, the Rhodes-Livingstone institute, which by the end of the decade had initiated a vigorous program of field investigation and publication.

The wealth of materials in monographic series and individual books precludes mention of more than a few of those which tended to consolidate and amplify earlier points of view. The appearance of a selection of the scientific papers of F. Boas under the title Race, Language and Culture in 1939 not only made many of his more important contributions more generally available than before, but was also a powerful reminder of the unity of anthropological science, and thus acted as a check against certain centrifugal forces resulting from specialization in its several branches. Pater W. Schmidt brought out his Handbuch der Methode der Kulturhistorischen Ethnologie (1937, published in 1939 in English translation), making available a systematic exposition of the position of the extreme diffusionist school. L. Lévy-Bruhl, before his death in 1940, published a final work in his series of studies of primitive mentality, L'Expérience Mystique . . . chez les Primitifs, wherein he somewhat modified the position he had previously held, and for which he had been criticized as unrealistic by anthropologists who had firsthand field experience with nonliterate folk. R. Thurnwald's five volume work, Die Menschliche Gesellschaft (1937), was an extended exposition of the position of this German functionalist; B. Malinowski, the better-known exponent of functionalism, before his death in 1942, completed a statement of his approach to the study of culture, which appeared in 1944 under the title A Scientific Theory of Culture, and Other Essays. A. L. Kroeber in 1945 published the results of his investigation of the problem of changing emphases in human civilization, entitled Configurations of Culture Growth, a work that at once gave rise to contro versial discussion.

In the field of ethnography, there could be noted the issuance in 1946 of the first two volumes of the *Handbook* of South American Indians, edited by J. Stewart, while in the same year J. R. Swanton capped the work of a lifetime with his definitive monograph, The Indians of the Southeastern United States. A. C. Haddon, whose death in 1943, like that of C. G. Seligman in 1940, was one of the major losses to English anthropology, published a summary volume on the work of the famous Torres Straits expedition.

The new lines along which students of culture began to direct their investigations were: (1) the study of the impact of convention on the individual; (2) the study of acculturation, with stress laid on contemporary culture-contact; (3) intensive study of the economic, political and legal institutions of primitive peoples and (4) applied or practical anthropology.

The study of personality and culture began with the earlier interest of E. Sapir in the problem of how the individual reacts to, and is shaped by his culture. With its emphasis on its cross-disciplinary character, involving, as it did, both anthropological and psychological techniques, it developed so rapidly that by 1946, in the U.S., at least, it was recognized as an important subdivision of anthropological enquiry. Its growth could roughly be divided into three stages. The first was essentially ethnological, and was concerned with the problem of cultural configurations. With this approach were associated the names of R. Benedict, whose book, Patterns of Culture, laid the theoretical base for the classification of cultures in psychological terms, and M. Mead, whose consolidated volume of earlier monographs, From the South Seas (1939), documented the approach with a rich store of ethnographic data.

Stress was next laid on the individual. A given culture was resolved into those basic disciplines which, operating in terms of primary and secondary institutions, were held to play on the developing personalities of the members of a society and thus made for their basic (later termed modal) personality structure. This point of view was set forth by A. Kardiner, a psychoanalyst, who worked in close association with R. Linton. Kardiner's initial book, The Individual and His Society (1939), was followed by elaborations of his thesis in other volumes, while Linton developed his point of view in a work entitled The Cultural Background of Personality (1945).

Relatively little field research was, however, carried on to test the hypothesis of the modal personality structure. An outstanding exception was the work of C. Dubois, among the Melanesian Alorese, published in the monograph entitled Alor (1944). The problem of developing methods by which personality types might be studied through field investigation led to the third stage in the development of personality and culture studies, where projective techniques, especially the Rorschach inkblot tests, were used. A number of students applied these tests, but the most consistent user was A. I. Hallowell, whose paper "The Rorschach Technique in the Study of Personality and Culture" (Amer. Anthr., 1945, pp. 195–210), summarized the status of work with this instrument and discussed its possible further application. (See also Psychology.)

Previous interest in the study of acculturation was extended in the U.S. by the appointment in 1934 of a committee of the Social Science Research council under the chairmanship of R. Redfield. This committee in 1936 published in various anthropological journals its definition of the term and an outline to guide research in problems involving culture contact. In 1938 a research memorandum entitled *Acculturation*, by M. J. Herskovits, further an-

alyzed methods and problems, and discussed existing studies. In England and the British colonies, the study of culture contact was encouraged because of the exigencies of the colonial problem, wherein anthropologists were called on, as B. Malinowski put it, to cushion the contact of natives with European culture.

Aside from practical considerations, the importance of the study of acculturation was realized to lie in the fact that the problems earlier studied as diffusion, whereby the borrowings resultant on contact between peoples were considered in terms of historical reconstructions, could be analyzed on the basis of actual occurrences, witnessed and set down by fieldworkers. The concept of a pure culture was thus given over in favour of a more realistic position concerning the ubiquity of contacts between peoples that had resulted in cultural change. In consequence, fieldwork more and more took into account all the data concerning a people, however mixed its culture might be, at the same time reconstructing, in more or less hypothetical form, the cultural "base-line" from which change began. A methodological offshoot of acculturation studies was the stress laid on an ethnohistorical attack. Ethnohistory, essential in studies of culture contact, combined ethnographic and archaeological findings with materials derived from historical documents bearing on a given contact between peoples. It thus afforded a surer factual basis for analysis of the processes involved than would otherwise be possible.

The importance of the study of economic, political and legal systems of primitive peoples was stressed in ethnographic as well as ethnological works. B. Malinowski, who laid emphasis on the integration of such data with other aspects of culture, was one of the first to underscore its im portance for an understanding of culture in general. R. Firth's Primitive Polynesian Economy (1939), following an earlier work, was more concerned with the application of economic theory to non-European cultures, as was D. M. Goodfellow's Principles of Economic Sociology (1937). which treated primarily of Bantu economy. R. Thurnwald's work already mentioned, which also appeared in an English version, envisaged a still broader approach with, however, an ethnological rather than an economic orientation. M. J. Herskovits' Economic Life of Primitive Peoples (1940) emphasized the theoretical implications of economic phenomena in nonmachine cultures. Many monographic studies appeared to make economic data from various parts of the primitive world available. Outstanding for the freshness of its approach was the work of A. I. Richards, Land, Labour and Diet in Northern Rhodesia (1939).

The study of law and political structures was not marked by any general works, though several papers by A. R. Radcliffe-Brown on the nature of primitive law acted as a stimulus to study, while the analysis of Cheyenne law by A. Hoebel and K. Llewellyn, The Cheyenne Way (1941), and of Tswana law by I. Schapera, A Handbook of Tswana Law and Custom (1938), did much to provide data on this aspect of primitive life. The work African Political Systems (1940), edited by M. Fortes and E. E. Evans-Pritchard, gave a useful overview of the political structures of Africa, and had an introductory chapter by the editors that was a distinguished contribution to the developing field of comparative politics.

Applied Anthropology.—Though latent in anthropological thought for many years, applied anthropology flowered during the decade under the impact of the war effort, when anthropologists were called on as never before to give of their knowledge of the far places of the earth in solving

many practical problems that arose in the course of global warfare. The use of anthropology in the administration of dependent peoples (as colonial tribes came to be called) was stimulated by the publication of Lord Haley's volume An African Survey (1938). "Practical anthropology," as it was termed in England, or "colonial anthropology" as it was named on the continent, received stronger governmental support than ever before. Anthropological training was given aspiring colonial officers on a broad scale, while more and more anthropologists were retained to study the problems of administering native peoples. The use of anthropologists in the Indian service of the United States increased. They were also employed in considerable number by the War Relocation authority. The volume by A. H. Leighton, The Governing of Men (1944), provided an effective account of how anthropological techniques were used in this situation. The application of anthropological methods in the study of problems of industry was urged, but its advisability was seriously questioned by many anthropologists. Two organizations devoted to applied anthropology were formed, the Society for Applied Anthropology, which published the journal Applied Anthropology, and the Institute for Ethnic Affairs, headed by John Collier. In Mexico, the journal America Indigena appeared, devoted to the discussion of practical problems of Indian administration in the Americas.

Races of Mankind.—Any classification of the races of mankind must rest on the major fact that all peoples of the earth belong to the same genus and the same species, Homo sapiens (Linnaeus). In other words, all people are fundamentally much more alike than they are different. There are, of course, certain observable outward differences in physical appearance, such as skin colour, hair colour and form, eye colour and so on. By using these criteria of different appearance, and about a dozen others, it is scientifically possible to divide mankind into major divisions (subspecies) and subdivisions (sub-subspecies). Most anthropologists call the former "stocks" and the latter "races." We may define race, simply, as a group set apart by a more or less definite combination of physical traits that are transmitted in hereditary descent. A stock becomes, accordingly, a certain cluster of races.

Scientists conventionally recognize three major stocks: Caucasoid, Mongoloid, Negroid, often referred to as White, Yellow and Black. Basically these are the peoples of Europe, Asia, and Africa and Melanesia, respectively. The use of the terms "White," "Yellow" and "Black" as the sole criterion of classification is not quite correct, for there

	I. I	Pigmentation	
Trait Skin	Caucasoid Pale ruddy white in N. Europe to light brown in S. Europe, to dark brown in India	Negroid Light brown to brown in E. Africa, dark brown to brown-black in W. Africa and Melanesia, the Bush- man is yellowish-brown	Mongoloid Quite generally light brown with a saffron undertone, to yel- lowish-brown
Hair	Light blond in N. Europe to blond and light brown in C. Europe, to dark brown in S. Europe and India	Uniformly dark brown to brown-black	Uniformly dark brown to brown- black
Eye (1) Pupil	Light blue in N. Europe to brown and dark brown in S. Europe and India	Uniformly brown to dark brown	Uniformly dark brown
(2) Sciera	Uniformly clear (white to bluish- white)	Tends to be mottled and flecked; yellow- ish-brown	Clear to mottled and flecked (not well known)
	II. Traits	of Head and Face	
Trait Head shape	Caucasoid Long, narrow, and high in N. Europe, to moder- ately long, broad and high in C. Europe and ladia, to short, broad and very high in S. E. Europe and Asia Minor	Negroid Tends to be long, narrow and moder- ately high, the Pygmies of Africa and Oceania tend to be shorter and broader headed	Mongoloid Tends to be moder- ately short, broad, and moderately high, though in N. China there is a tendency to long- headedness
Hair form	Straight in N. Europe to wavy and slightly curly in S. Europe and India	Wavy to curly in E. Africa to woolly and frizzly in W. and S. Africa and Oceania	Uniformly straight
Hair texture	Fine in N. Europe to medium in S. Europe and India	Uniformly coarse and wiry	Uniformly very coarse
Eye fold	No fold is the rule, but a lateral vertical fold often occurs in N. Europe	A medial vertical fold is often found in W. Africa, the Bushman have a very charac- teristic, upper lid overhang	There is a marked tendency to a medi- al epicanthic fold (so-called "Mongo- lian" eye fold)
Ear	Generally of moder- ate size, with good "helical roll"	Generally small, with poor "helical roll," the Bushman ear has very little roll and appears "crumpled"	Generally of moder- ate size, with good "helical roll"
Face (1) Height	High in N. Europe to medium in S. Europe and India	High in E. Africa to medium in W. Africa and Oceania	Medium in N. China to low in S. China and some Japanese
(2) Breadth	Narrow in N. Europe to medium in S. Europe and India	Narrow in E. Africa to medium in W. Africa and Oceania	Broad in Asiatics gen- erally to very broad in some Amerinds.
(3) Cheek- bones	Generally compressed and not projecting	Generally compressed and not projecting, in the Bushman are broad and "high"	Uniformly arched and projecting for- ward to give "high" cheekbone
(4) Contour or profile	Uniformly straight as seen from side	Generally slants down and forward as seen from side	Generally straight as seen from side
Nose (1) Root	Uniformly high and narrow	Moderately high and narrow in E. Africa to low and broad in W. Africa	Tendency to moder- ately low and broad
(2) Bridge	Straight in W. Europe, S. Europe and some peoples of India, con- cave in N. E. Europe, convex in S. E. Europe and Asia Minor	Tends to be straight to weakly convex; uniformly low	Tends to be straight, broad and low
(3) Wings	Uniformly narrow to moderate	Moderately narrow in E. Africa, very wide in W. Africa and Oceania	Tends to be moder- ately broad
(4) Nostrils	Tends to be an oval, with long axis antero-posterior	Rounded in W. Africa, to transverse oval in E. Africa	Generally an antero- posterior oval, but tends to rounded in S. China
(5) Tip	Directed forward in N. and S. Europe and India, upwards in N.E. Europe, downwards in S.E. Europe and Asia Minor	Directed forward in E. Africa, but thick and rounded in W. Africa and Oceania	Generally directed forward, with tend- ency to slight down- ward inclination
Mouth (1) Opening or fissure	Generally moderately broad	Generally moderately broad	Moderately broad in Asiatics to very broad in some Amerinds
(2) Lips	Thin in N. Europe, to moderately thick in rest of Europe and India	Moderately thick in E. Africa to very thick and everted in W. Africa	Generally moder- ately thick

Table I.—(continued) III. General Body Traits

Trait Stature	Caucasoid Tall in N. Europe and N.W. India, moder- ately tall in C. and S.E. Europe, short in S. Europe and rest of India	Negroid Tall in E. Africa, moderately tall in W. Africa and Oceania, very short (dwarfed) in Pygmies of Africa and Oceania	Mongoloid Tall in N. China and some Amerinds, but short to moderately tall elsewhere
Body hair	Generally profuse, especially in S.E. Europe and among Ainu; S. Europe smoother skinned	Uniformly scant	Uniformly very scar
Vertebral column	Strongly S-curved, with marked lumbar curve	Moderately S-curved, with weak lumbar curve	Intermediate be- tween Caucasoids and Negroids
Pelvis	Broad, shallow	Narrow, deep	Moderately broad and deep
Limb pro- portions	Arms and ^l egs not disproportionately long	Arms and legs long relative to trunk; fore- arm and lower leg relatively long	Legs tend to be short, relative to trunk length, other- wise limb segments not disproportionate
Breast form	Hemispherical	Conical	Disk-shaped
Buttock contour (female)	Generally prominent	Moderately prominent to very prominent (Bushwomen are steatopygous)	Moderately prominent
General body build	Generally muscular with tendency to heaviness	Generally muscular, but with marked linearity in E. Africa	Uniformly muscular

is a considerable range of variation within each stock. In fact, any single stock—and even more so, any given race—cannot be defined by a single physical trait, or even two or three. It is a combination or complex, relatively unique to the stock or race that sets it apart.

In Table I, the physical characteristics of the three stocks are given. It will be noted that in most instances each single trait is so variable that it cuts right across stock lines. This drives home the point made above, namely, that all traits must be used in setting up a stock. In the table, therefore, the three major stocks are defined by reading the columns vertically, not horizontally. For example, there are "white" Caucasoids who are brown-skinned, and "black" Negroids that are light brown in skin colour; similarly there are long-headed Caucasoids and long-headed Negroids, and there are round-headed Caucasoids and round-headed Mongoloids; or again, there are very tall Caucasoids in Denmark, very tall Negroids in East Africa, and very tall Mongoloids in Tierra del Fuego. For each trait it can be demonstrated that variability is so great that a single trait has little or no diagnostic value. True, there are no really white Negroids, or really black Caucasoids, but it is still well-nigh impossible to define a stock, or a race within a stock, by one or two traits. That is what is meant by saying that reading Table I horizontally will not serve to classify a stock.

Now, still observe Table I. Each stock can be defined by the summation of traits vertically listed in the appropriate column, *i.e.*, Caucasoid, Negroid, Mongoloid. It is the aggregate, the complex, of all the traits that is used in stock diagnosis. On this basis, science validates the definition of the three major stocks of mankind.

What has been demonstrated so far concerning stock variability is of importance in the classification of races within each stock. It is only because mankind is so variable—even though all human beings belong to the species *Homo sapiens*—that he can be logically and fairly accurately divided and subdivided into major groups (stocks) and minor groups (races).

Each stock has been divided into many or few races, depending upon the author consulted, or the state of knowledge concerning the group in question. In Table II there is presented a racial classification that is generally acceptable to modern physical anthropologists.

An inspection of Table II reveals that more is known about the Caucasoids than the Negroids, and more about the Negroids than the Mongoloids—indeed, knowledge of the last was still very inadequate at the end of the decade 1937–46. Knowledge of the Caucasoids—the peoples of Europe—was sufficient to permit several conclusions: (1) there is no "pure" race; (2) no single state or nation is composed of a single race; (3) all peoples of Europe are the product of an age-old mixture of races.

The Germans, for example, are a composite of Nordic, Mediterranean, Alpine, Dinaric and east Baltic; the English show traces of Nordic, Alpine, Dinaric and Medi-

	Table II.—The Races of Mankind								
	I. Caucasoids								
	Race	Habitat							
1.	"Archaic" or primitive Cauca- soids	These are the Ainu of Japan and the Australian aborigines. The latter, referred to as Australoids, are a racial element in the peoples of Melanesia; there is some Negroid admixture.							
2.	Mediterranean	S. Europe generally; also in N. and N.E. Africa, and a basic element in Asia Minor (Arabs) and N. India; found sporadically in C. Europe (e.g., Wales); probably the original Caucasoid race.							
3.	Alpine	C. Europe generally, extending east to the area of the Slavic- speaking peoples.							
4.	Nordic	N. Europe generally, especially in Scandinavia, N.W. and S.W. Germany and the British Isles; found sporadically in C. Europe (e.g., Holland).							
5.	East Baltic	Found in the circum-Baltic area of N.E. Europe; is the basic element in the Finns and the Lapps, both of whom—especially the latter—show Mongoloid admixture.							
6.	Dinaric	S.E. Europe generally: the Balkans and the Caucasus.							
7.	Armenoid	In Asia-Minor: Anatolia, Iraq, Iran.							
8.	Indo-Afghan or East Indian	In Afghanistan and the northern half of India, especially N.W. India, basically a pigmented Mediterranean type.							
9.	Polynesian	In the Pacific islands: Samoa, New Zealand, Hawaiian Islands, Marquesas, Easter Island, the Polynesians are basically Cau- casoid, but there is some Mongoloid and a slight Negroid admixture.							
11 Negroids									
		II. Negroids							
	Race								
1.	Race Hamitic, or Ethiopian	II. Negroids Habitat N.E. Africa: Ethiopia, Somaliland. The type is a mixture of Mediterranean (Caucasoid) plus Nilote (Negroid).

3. Siberic	The peoples of Siberia.					
4 7	The end of control Adv. Adv. 19					

4. Turkic The peoples of central Asia and Mongolia.

 Malayan Java, Sumatra, Bali, the Philippines; this is probably the Mongoloid element in the Polynesians.

6. Eskimo N. America, from Alaska eastward to Greenland.

 Amerindian N., C. and S. America; the Amerindian is divided into a number of geographical races.

terranean.

It is best, therefore, to speak of "racial elements," "racial types." or "racial strains," in any given European population.

Europe is, of course, the Caucasoid nucleus. North Africa is the Caucasoid-Negroid contact zone (Hamitic), and central Asia is the Caucasoid-Mongoloid contact zone (Turkic).

In each of these two areas the peoples show transitional types between the two major stocks involved. These transitional types are due, according to some anthropologists, to evolutionary intermediacy, but according to most authorities they represent the results of mixture between races and stocks (W. M. K.)

In 1931, the opening of a smelter in Texas, using Mexican ores, had started a shift from China as the chief source of antimony for consumption in the United States. Although China was still the world's largest producer in 1939, the Japanese invasion cut down activities there at the same time that war in Europe was increasing the demand.

As a result, Bolivia and Mexico began to furnish most of the supply. Demand reached its peak in 1942 and 1943, with heavy subsequent declines to prewar levels

*Antimony content of antimonial lead, produced from foreign and domestic ores. †Estimated antimony content of alloys, oxide and liquated sulphide.

Even the demand created by World War II could not build up an appreciable U.S. domestic output of antimony ores; the bulk of the domestic recovery was from concentrates separated from complex ores containing gold, mercury, copper, or tungsten, or from lead-antimony ores that went to smelters of antimonial lead. With the ending of war demand, low metal prices and increasing costs of operation shut down several of the smaller smelters. The same causes led to heavy cuts in output in countries exporting ore to the United States, and in 1946 the shortage of antimony became as acute as at any time during the war—so much so that it became difficult to supply storage batteries for automobiles.

Anti-Semitism

Anti-Semitism was one of the important social and political forces of the decade 1937–46. Its impact upon Jews resulted in the extermination of one-third of the nearly 16,000,000 of them who had lived in many nations of the world before the rise of Adolph Hitler in 1932. But the nazi use of anti-Semitism as a political weapon in countries other than Germany was a new phenomenon in history. Spearheaded by the indoctrinated international agents of National Socialism, anti-Semitism came to be one of the distinguishing marks of most of the political fronts for fascism in countries like the United States, England and the Latin American nations. It was designed

Street car marked with the Star of David for ghetto dwellers in Warsaw, Poland, during World War II

Typical German raid on the ghetto in Warsaw during the nazi occupation of World War II. The Jewish population of this area was virtually wiped, out before Germany's final defeat

by the Hitler strategists to be used as a divisive and cor-10sive force in the democratic or near-democratic states.

Patterned by the nazi plan, Jews were linked with international communism while fascism, though not always called by its simplest name, was usually portrayed as the defender of western civilization against the "Red" menace. Thus, by indirection, many were drawn into support of anti-Semitic movements, which were really movements directed against the fundamentals of democratic life.

Philosophy of Anti-Semitism.—The philosophical basis of the wave of anti-Semitism was also different. It was peculiarly Teutonic in character. Persecution of Jews was nothing new in world history in 1937. But previous persecutions had been very largely inspired by religious fanaticisms. The dissolution of church and state in modern societies and the general decline of religious fanaticism had held promise for a gradual diminution of anti-Semitism. The mediaeval concept of Jews as a racial or religious nation within other nations was being gradually dissolved in the democratic systems which granted individual rights, regardless of man's racial derivations or religious beliefs.

Perhaps cognizant of these advances, nazi anti-Semitism was projected upon a different philosophical platform. Naziism revived the mediaeval concept of the racial state. Those who were Aryans were acceptable for citizenship. Any who were not Aryans were automatically barred from citizenship. This doctrine had achieved legal sanction and definition in 1935, in the Nuernberg laws, although it had had less far-reaching antecedents in decrees from 1933, when Hitler had come to power. The Nuernberg decrees, declaring "that the purity of the German blood is prerequisite for the future existence of the German people" deprived Jews of all rights of citizenship, forbade intermarriage, denied Jews the right to display the reich or national flag, denied Jewish institutions the exemption from taxation granted public institutions of other faiths, denied all children of Jewish faith the facilities of public schools, etc.

Here, it is worth observing that although the nazi propaganda made much of racial differences of Jews, the leaders of the movement were sometimes hard pressed by realities in the detection of such differences. They resorted to a number of artificial and arbitrary devices. One of the most far-reaching was the decree which compelled everyone who had one grandparent of Jewish faith to call himself a Jew, subject to the discriminatory laws. Jews were compelled to adopt "Jewish" names and to carry identification cards, stamped with a red "J."

All of this "legal" procedure reached a climax and poured over into more violent action in 1938. In November of that year, a half-crazed Jewish boy, a national of Poland, shot Ernst vom Rath, third secretary of the German embassy in Paris. Two days later, vom Rath died. The nazi party then launched the policy of liquidation and extermination which it continued wherever it had power, until the end of the war in 1945.

The alliance of this concept of a racial state, which made Jews racially aliens, with the mystery and fear of communism and the identification of communism as a "Jewish" doctrine, provided a powerful political weapon for any who sought to exploit the sense of insecurity of middle-class groups, whose confidence had been so severely shaken by the deep and prolonged economic depression of the early '30s. The myth of fascism "getting things done" was a powerful factor in giving support to movements which inspired by naziism and sometimes internationally financed by it, were anti-Semitic in character. It was not uncommon to hear the uncritical and unconvinced comment, "Well, maybe Hitler can't be entirely wrong."

Consequences.—The impact of these doctrines varied in accordance with the vitality of democracy or its weakness in any given nation. It was severest in Germany, where this kind of racial anti-Semitism had had a long career as a political instrumentality from the days of Bismarck and the beginning of Germany's not yet realized nationalization. As the Hitler armies moved across Europe they brought with them the Nuernberg decrees or reasonable facsimiles of them. The ethnic-racial-religious bases of many of the central and east European states had long made them anti-Semitic societies. The stimulus of German anti-Semitism, the widespread propaganda machine of fascism and the early successes of Hitler encouraged a

Jewish women slave workers marked with the yellow cross, liberated by troops of the U.S. 9th army near Kaunitz, Germany, in 1945. These girls had been brought from nazi conquered countries and made to work in an ammunition plant

rising tide of anti-Semitism in these ethnically conscious states.

By 1937, the influence of National Socialism was being felt in all the countries of central and eastern Europe. Following the Anschluss in March 1938, the Nuernberg laws were introduced in Austria within two months. In June 1939, following the occupation of Bohemia and Moravia and the granting of "independence" to Slovakia, the nazi legislation was gradually introduced into what had been Czechoslovakia. In Poland and the Baltic states the blitzkrieg of 1939 brought terror to the Jews of those countries, and the stunning fall of the Low Countries and France in 1940 completed nazi control of the continent and sealed Europe's Jews in an inferno of hate about which little could really be learned and only the worst could be feared for five agonizing years. Not for five hundred years, after the Spanish Inquisition, had such stark unmitigated tragedy overtaken so many Jews. And this exceeded that earlier period in extent and irrevoca-

For if the Jews of 15th century Spain could avoid the wrack by conversion, those of 20th century Europe could not evade the arbitrary Hitlerian theories of race. When the curtain had lifted in May 1945, the Jewish population of the European continent, which had numbered about 9,000,000 in 1932, had been halved. The full intensity of that tragedy can be appreciated only when it is realized that nearly 4,000,000 Jews of soviet Russia were not included with those who suffered as victims of anti-Semitism. Elsewhere in the world these doctrines were not without reverberations, although their implementation and effect never reached anything like the condition on the continent.

During the initial successes of fascism, the U.S., England and the Latin American nations were treated to a plethora of "shirt" movements and "nationalistic" cults, practically all of which were either avowedly or philosophically anti-democratic. In most of them anti-Semitism was a major propaganda device. Except for a few isolated incidents there were no physical attacks on Jews, and none of the established democratic states enacted or even seriously considered legislation of a discriminatory nature. There were some anti-Semitic speeches in the congress

of the U.S. and in the English parliament, but there is no evidence that any credence was given them by the membership of these legislatures. In the U.S. several openly anti-Semitic spokesmen were aspirants for public office, but there was apparently a widespread gulf between their popularity at mass meetings and their popularity at the polls. While there may have been anti-Semites in public office, there was no known successful candidacy by any person who used anti-Semitism as a political plank.

In England and the nations of the western hemisphere, the impact of European anti-Semitism was therefore mostly psychological. To some immeasurable extent it may also have spilled over into social relationships between Jews and those not of Jewish faith. Numerous polls, conducted by several of the public opinion sampling organizations all seemed to prove little, in any attempt to measure this highly intangible and elusive phenomenon.

All that could accurately be said is that there was a considerable increase of anti-Semitic activity and propaganda. But whether or not this proved that there was any comparable increase of anti-Semitism was a moot question. For at least some of the financial support for such propagandists and their movements was known to have been imported from Germany, as for example, the German-American bund. Therefore, these did not require grassroots support in the U.S. or England. Many of the less obvious anti-Semitic organizations drew innocent people into movements which advertised themselves as American" or "anti-communist" or "pro-Christian" and muted their anti-Semitism or ware actific muted their anti-Semitism or were anti-Semitic only by indirection. Rather than a "movement" there was apparently a confusion of propagandists, lunatic-fringers, charlatans and political crackpots, most of whom were in vigorous competition with each other. In England the blackshirted movement of Sir Robert Mosley came to a quick and decisive end when Mosley was jailed in the early months of World War II, and the entrance of the U.S. into the war against fascism made anti-Semitism in any overt form suspect and unpopular.

Many students of the problem claimed a perceptible increase in what they called "social" anti-Semitism: the barring of Jews from private clubs, certain hotels mostly of a resort nature, and a general reluctance on the part of Christians to mix socially with Jews. But such charges were difficult to prove. Much of an individual's opinion in any such undemonstrable situation depended upon personal experience and perspective. If there was an increase of such anti-Semitism, at the same time a number of serious efforts were made to stamp it out. The more reputable newspapers in the larger metropolitan centres voluntarily adopted policies of refusing advertising that was obviously discriminatory. While some advertisers practised evasions, there was an almost complete elimination of the "gentiles only" type of ad. At least one state passed a law forbidding resorts to advertise that Jews were unwanted.

Countermeasures.—Any survey of or reference to the organizations which fed anti-Semitism and lived upon it would be only a fragmentary picture. For if there appeared to be an increase in anti-Semitic activity, there was also an increased awareness of the essentially reactionary nature of anti-Semitism and the fundamental nature of its threat to democratic institutions. If Hitler had successfully used anti-Semitism as a political wedge in the nations of Europe, in England and the U.S. that fact had not escaped notice.

Powerful campaigns against anti-Semitism, designed for the most part as educational programs about Jews, were sponsored by numerous nonsectarian or entirely Christian organizations. As vigorously as the anti-Semitic movements pressed their cause, others advanced the argument that anti-Semitism was un-American. "Brotherhood Week" became a national institution in the U.S. in which representatives of Catholicism, Protestantism and Judaism cooperated. The National Conference of Christians and Jews inaugurated a nation-wide program. The pope condemned anti-Semitism, by reminding the Christian world that "spiritually, we are all Semites," and in the summer of 1946, there was a dramatic inter-faith meeting of world-wide proportion in England.

Even during World War II, stories drifted back from Europe of men and women who defied death to demonstrate a sense of fellowship with Jews and a realization of fascism as the common enemy of freedom-loving men of all races or creeds. Many of those who escaped from the continent did so through assistance given by Christians at the peril of their own lives.

In the Netherlands and Czechoslovakia, Christians put on the Jewish badges which the Jews were compelled to wear. In Rome, the chief rabbi of Italy was converted to Catholicism out of a sense of gratitude for succor given Jews during the years when Hitler had dominated the country.

During the war most of the resistance and underground movements conducted campaigns against anti-Semitism as important parts of their programs. At the end of the war it became known that so many Jewish children had been adopted into Christian homes and thus sheltered from the nazis that leaders among Jews were disturbed that many would be lost to their faith.

Aftereffects.—By 1946 the status of anti-Semitism was a moot question in practically every nation of the world in which Jews lived. One could make out a good case to show that it had increased. One could as easily make out as good a case to show that if it had increased, there had also been a corresponding increase of opposition to it and recognition of it as a problem which challenged all liberal men to find a solution lest some future demagogue use its corrosive powers to split men asunder, as Hitler had done.

There was no doubt that it had passed its peak in Europe. As nazidom crumbled, its satellites ran for cover and most of them officially repudiated their own versions of the Nuernberg laws. It was difficult to ascertain how deeply there had seeped into the populations the awareness of anti-Semitism as an undemocratic force. But governments were on record for equal treatment for Jews.

The general chaos of reconstruction left a wide divergence between such official pronouncements of governments which were in many instances still too feeble to enforce them and the actions of scattered elements of the populations. In addition the tug and pull of parties contending for control of the newly formed governments left the way open for some political aspirants to attempt to use anti-Semitism as a political tool, in the manner of Hitler. Such seems to have been the situation in Poland, for example, where pogroms were reported in the summer of 1946. Yet, despite these discouraging incidents, there was encouragement in the fact that the Polish government recognized the world's antipathy sufficiently to disclaim any connection with the attacks and to attempt to bring the attackers to speedy and stern justice. This was progress over a prewar Poland where anti-Semitism was a recognized and sanctioned policy of the state.

The reconstruction of the lives of Jews seemed to follow the general pattern of reconstruction in the Netherlands and Belgium and France, unimpeded by discrimination of a serious nature. Here and there, traces of the Hitler occupation could be seen. But in general, collaborationists were summarily dealt with.

The nations of central Europe were faced with serious and fundamental problems which might well determine the future of anti-Semitism in that part of Europe where it had long been most virulent. Czechoslovakia, for example, determined that it could no longer recognize national-minority groups. The new Czech government was to be built upon the system of individual rather than minority rights. This would necessitate an end to concepts of Jewish nationalism and segregation, in anything but religion; a dissolution of the old European form of a Jewish community, enjoying varying amounts of semiofficial recognition and autonomy. Into the United Nations charter, largely at the instigation of Jews, there had been written the promise of guarantees of individual human rights. The desire or ability of the infant United Nations to define and implement this promise would also have a bearing on anti-Semitism in the future.

This extension of systems of individual rights, supplanting systems based upon group or minority rights, was raising new aspects of the problem of anti-Semitism. A clear-cut distinction seemed in the making whereby on the one hand opposition to so-called "Jewish communities," *i.e.*, corporate Jewish life in matters other than religion, would have to be differentiated from discrimination against individual humans who were Jews. Even traditionally liberal and democratic governments like Czechoslovakia were pursuing policies designed to liquidate "nations within nations."

There was a young and fragile hope that the libertarian principles of the French Revolution might finally prevail in those parts of Europe where they had not penetrated in a century and a half. If they did, the problem of anti-Semitism would slowly be lessened but not until Jews responded to the criterion set down by the liberals of the first republic on the continent, "To the individual Jew everything; to the Jews as a nation, nothing."

Meanwhile, the insistence on Jewish "nationhood" and the rights of Jewish "nationhood" to political autonomy in a state of its own in Palestine, advanced by one segment of Jews known as Zionists, was creating anti-Semitism in a new part of the world. The Semitic Arabs were becoming vigorously and articulately anti-Zionist with the threat of becoming anti-Jewish in 1946. For the first time in history there were anti-Jewish riots in Cairo in the winter of 1945–46. There was danger then, that having passed its crest in Europe, anti-Semitism would find new life in the newly important near east.

In the U.S. there was unquestionably latent anti-Semitism. No leader had emerged to forge or attempt to forge the latent feeling into a movement. Meanwhile, the country was not unaware of the danger. The Ku Klux Klan (q.v.) anti-Semitic, anti-Catholic and anti-Negro organization of the 1920s, attempted a revival in 1945–46 and was met by vigorous legislative action depriving it of the right to a charter in several states. Legislation outlawing discrimination in employment opportunities was passed in an attempt to root out the economic causes of anti-Semitism.

But a not inconsiderable element in the status of anti-Semitism in 1946 was the attitude of Jews themselves. The impact of the dark decade upon their lives had been fearful. Many were discouraged with the process of

emancipation and the struggle for equality. They had been driven back upon themselves, and segregation and isolation seemed to predominate in most of their thinking and activity. They were drifting into the mediaeval pattern of a nation within the many nations in which they lived at the very time when the world was rejecting such social structures. Herein lay the possibilities of another vicious circle; of separation and withdrawal from society; of growing estrangement, suspicion, dislike of difference and violence, so that given an economic collapse, another war or any of the other major cataclysms which men so often had sought to escape by beating a scapegoat, a new wave of anti-Semitism would unleash furies that might surpass any the world had yet known.

* * *

In 1946 the chapter in the history of anti-Semitism that had begun in 1933, that had reached its peak from 1938-45, was still unfinished. The conclusion would depend upon what both Jews and Christians had learned in the ten years then passed. There was little doubt that many powerful forces of separateness, segregation and friction were left as part of the debris of war. The world could drift to another cataclysm in which anti-Semitism, nurtured by Hitler, would be fiercer and more widespread than ever. Or the world could build if both Jews and those of other faiths laid the ghost of Hitler along with his armies and, rising above exclusionary romanticisms of race and nation and "peoplehood," joined hands in an integrated effort to make the one world in which all lived a human reality which would square with the scientific and economic facts of mankind's new atomic age. Antonescu, Ion

Antonescu (1882–1946), Rumanian soldier and politician, was born June 2, 1882, in Transylvania. After service with the Rumanian armies in World War I he was military attaché in London and Rome, later rising to chief of the army's general staff and war minister. German demands on Rumania early in World War II led to serious internal disorders, and King Carol was compelled to offer the premiership to Antonescu, whose pro-nazi sentiments were well known. Upon taking office Sept. 5, 1940, Antonescu demanded Carol's abdication, established a totalitarian regime and ruled as an absolute dictator. Rumania soon became a German satellite and on June 22, 1941, joined in Germany's war against the soviet union. Antonescu assumed the title of generalissimo and commander of Rumanian armies in Bessarabia. During the soviet counterattack which penetrated Rumania in 1944 Antonescu was arrested by King Michael I, who had succeeded his father Carol to the throne, and in Sept. 1944, Antonescu and other Rumanians accused of active collaboration with the nazis, were turned over to soviet military authorities. After a ten-day trial in a Rumanian people's court, Antonescu and 12 of his associates were convicted May 17, 1946, on charges of war crimes and sentenced to death. He

Aosta, Duke of

Amedeo (1898–1942), duke of Aosta, Italian general, was born Oct. 21, 1898, in Turin, Italy, the son of Prince Emanuele Filiberto, duke of Aosta, and Princess Helen of France. The duke was a cousin of King Victor Emmanuel and was head of the house of Savoy-Aosta, second branch of the Italian royal family. At 17 he entered the army as a private in the artillery and saw active service at the front during World War I. He rose rapidly through the ranks, was decorated many times, and enjoyed wide popularity among all classes of Italians. A firm fascist, he was a close friend of Benito Mussolini. In 1937 he was named viceroy of Ethiopia, succeeding Marshal Rodolfo Graziani. During the period of British attacks on Ethiopia, 1940-41, he directed the Italian forces and won promotion to general of the Italian air force. In May 1941 the duke of Aosta, with a force of 7,000 surrendered to British troops at Amba Alagi after a long siege. He died while still a prisoner of war at Nairobi, Kenya, on March 3, 1942.

Aquariums

The years 1937-1946 were eventful for public aquariums. Not only were many of them closed or destroyed, but at least one major development from the standard assemblage of glass-fronted tanks was assayed. This was at the Marine Studios, St. Augustine, Fla., where two large pools were constructed to enclose segments of the ocean bottom and its immediate overlying water and the inhabitants thereof.

The basic difference between this and other institutions, aside from the size and situation of the viewing panels, at the sides and underneath the pools, was the attempt to carry in one large body of water from the nearby ocean numerous species of fishes usually antagonistic to each other or, at least, fishes which normally prey one upon the other, and to have the whole affair open to the sky.

Numerous technical difficulties appeared, including that of keeping such amounts of uncovered water at suitable temperatures. The normal efforts of certain fishes to live off other species of fishes entailed considerable replacement of specimens—replacements which could be effected in some locations but would be prohibitive in most others. This institution, depending entirely on admission fees for its maintenance, became a casualty when gasoline rationing restricted tourist traffic in 1942. It was re-opened in 1946 on a somewhat curtailed basis, only one tank being put into operation. All of the exhibits of this major development of fish exhibiting were of local origin.

Standard types of public aquariums throughout the world had a somewhat disastrous time during World War II. Not only were their sources of exhibition material cut to a minimum, or cut off entirely in many cases, but many of them either suffered severely from bombs or were closed as a measure of public safety, those in Europe suffering particularly. In the United States, most aquariums managed to keep open, although their exhibits became scant, and many species of fishes disappeared from their tanks entirely. This was particularly true of the marine specimens, collections of which were either prohibited or impossible to obtain.

One major institution was closed permanently—the New York aquarium housed in the old Castle Clinton, the Battery, New York city. The closure on Oct. 1, 1941, was declared necessary by the city, in order to provide for new construction in Battery park. It was not the oldest aquarium in the world, but it was certainly the most popular, more than 84,000,000 visitors having been entertained there in its 43 years of existence. Its collections were distributed among other public aquariums, returned to the ocean or planted in nearby fresh waters. The research activities conducted in the institution were carried on in accommodations loaned to the managers, the New York Zoological society, by sister institutions, and an interim exhibition was established in the New York Zoological park, pending the construction of a new building.

A small aquarium, specializing in local fresh-water species and in specimens from tropical fresh waters of the world was opened in Druid Hill park, Maryland, a joint venture of the Maryland Fish and Wildlife commission and the Baltimore Aquarium society.

Numerous cities projected plans for aquariums to be built as soon as practical after the war, both in the United States and in Europe, and it was of great interest to note that many of these were being planned either as adjuncts to marine research stations or as research stations per se, the exhibition of the fishes being subordinated to more serious work on the study of fishes and other marine organisms as a source of food and of the ocean as a source of the raw materials for industry. (C. W. C.)

Aqueducts

In the U.S. the Metropolitan aqueduct (241 miles) was constructed in 1943 to deliver Colorado river water, regulated by the bureau of reclamation's Boulder and Parker dams, to Los Angeles and 12 other California cities. This aqueduct, extending from Parker dam to Cajalco reservoir, 12 miles south of Riverside, Calif., was built at a cost of \$200,000,000 by the metropolitan water district, comprising these 13 municipalities. The capacity of the system was 1,000,000,000 gallons per day.

During 1945, the United States bureau of reclamation engineers prepared the designs and specifications for the 71-mi. San Diego aqueduct, under construction by the navy department in 1946, to deliver 50,000,000 gallons of Colorado river water daily to San Diego. The aqueduct was built to connect with the metropolitan water district's Colorado river aqueduct near San Jacinto, Riverside county, Calif., and to deliver water to the San Vicente

reservoir owned by the city of San Diego, and located approximately 16 mi. northeast of that city. Seven contracts were awarded for the construction of the aqueduct, involving the excavation of Poway, Fire Hill, San Vicente, Rainbow, Lilac, Red Mountain and Oat Hills tunnels and the laying of precast concrete pipe varying from 48 in. to 96 in. in diameter.

The 41-mi. Salt Lake aqueduct was also under construction by the bureau of reclamation on the Provo river project (Utah), to tap Deer Creek reservoir, located on the Provo river about 16 mi. northeast of Provo, Utah, and provide water for industrial and domestic purposes in Salt Lake City and, in addition, serve irrigation needs. This conduit, with a capacity of 150 sec.-ft. and comprised of tunnels, reaches of 69-in. inside diameter precast concrete pipe line and plate steel pipe line of various lengths, was approximately one-half complete in the fall of 1946.

The Olmstead tunnel, 6½ ft. in diameter and 3,600 ft. long, was completed in Nov. 1939 and the 3-mi. Alpine-Draper tunnel, also a part of the aqueduct, was completed in Nov. 1941. For the construction of the first 9-mi. section of this aqueduct, an aggregate processing plant was required near American Fork canyon, and a pipe-manufacturing plant was built at Pleasant Grove, Utah, by the contractor, the Utah Concrete Pipe company of Salt Lake City. Ten pipe units, 20 ft. long with a 69 in. inside diameter and 7½ in. wall thickness weighing approximately 20 tons each, could be manufactured daily at this pipe manufacturing plant.

Another water conductor on which construction was suspended during World War II by the bureau on the Provo river project, was the 6-mi. Duchesne tunnel, to divert water for irrigation purposes from the upper tributaries of the Duchesne river (Colorado river watershed) to the Provo river for storage in Deer Creek reservoir. The tunnel, located about 30 mi. northeast of Deer Creek reservoir, was designed for a capacity of 375 cu.ft. per second when unlined and a capacity of 600 sec.-ft. when lined with concrete. Approximately 9 ft. 3 in. in diameter, it required permanent steel rib liner supports and steel tunnel-liner plates in some places.

The first part of the Delaware river aqueduct system to supplement New York city's water supply was completed in the spring of 1944 when the delivery of water through the long tunnel from Roundout valley was begun. The completed aqueduct was to be 85 mi. long, and would supply the city with 540,000,000 gal. of water daily.

Previous to the completion of the initial stage of the aqueduct, New York city received its water supply, about 1,000,000,000 gal. daily, from the Croton and Catskill reservoirs, which eventually proved inadequate. The lack of precipitation on the existing watershed and the fact that its capacity had been reached several years before were primarily responsible for undertaking the construction of the Delaware river aqueduct system.

Work on the project was drastically curtailed during World War II because of lack of men and materials. As a result Merriman dam, which was to form Roundout reservoir, was not completed by the end of the decade; nor were the dams on the upper tributaries of the Delaware river which were to form the other two reservoirs in the system, the Neversink and East Delaware. The major part of the water supply was to be tunnelled through the aqueducts from these reservoirs.

Considerable aqueduct construction work was under way at the end of the decade 1937–46 on the bureau's

Colorado-Big Thompson project to deliver water from the western or Pacific slope of the Rocky mountains to the eastern side for supplemental irrigation of 615,000 ac. of land in northeastern Colorado. The 13-mi. Alva B. Adams tunnel, cutting through the backbone of the Rocky mountains from Grand lake, Colo., was the longest irrigation tunnel in the world at that time. It was completed early in 1946, and construction was begun on the 13-mi. Rams Horn and the 1.1-mi. Prospect Mountain tunnels, respectively 10 ft. and 121/2 ft. in diameter with capacities of 550 and 1,300 sec.-ft. respectively.

These two tunnels, together with the 1.3-mi. Aspen Creek siphon, a 10 ft. 9 in. diameter conduit connecting with the east end of the Alva B. Adams tunnel, formed a part of the power canal No. 1, terminating at the Estes Park

power plant near Estes Park, Colo.

The All-American canal, a part of the Boulder canyon project, tapped the Colorado river at Imperial dam downstream from Boulder dam. This 80-mi. canal, completed in 1940, served approximately 500,000 ac. of irrigable land in the Imperial valley of California, extending from Imperial dam down to the Mexico border line east of Yuma, Ariz., then along the U.S. side of this boundary line to the West Side Main canal west of Calexico, Calif. It became the largest man-made river in the world with an initial capacity of 15,155 sec.-ft.

The Coachella canal, a 145-mi. branch of the All-American canal system, was under construction by the bureau

The Colorado river aqueduct, a 241-mi. waterway supplying southern California. The photograph shows construction work as it neared completion on a giant intake manifold

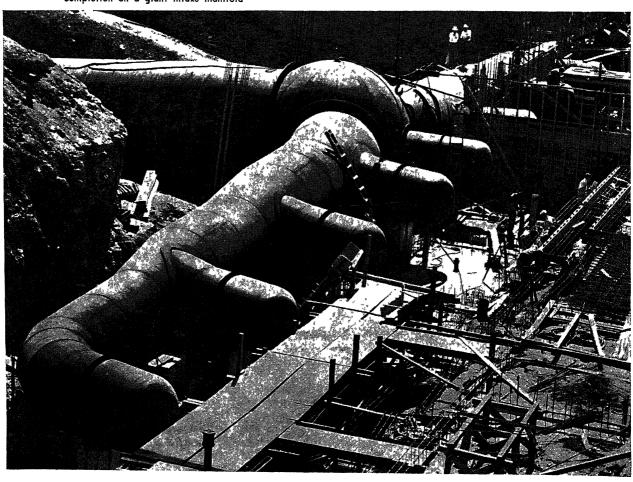

at the end of 1946 to serve irrigation needs of approximately 75,000 ac. of land in the Coachella valley of California. Branching from the All-American canal at a point approximately 18 mi. east of Yuma, Ariz., it was to extend northwest as far as Indio, Calif. Approximately 84 mi. of the Coachella canal had been completed in the fall of 1946, and work on 27 additional miles was progressing. This canal, designed for an initial capacity of 2,500 sec.-ft., was 60 ft. wide at the bottom, 124 ft. wide at the top and approximately 16 ft. deep at the taking-off point from the All-American canal.

The canal system of the multimillion acre Central valley project under construction by the bureau of reclamation in California was to consist of the Madera canal, the Friant-Kern canal, the Contra Costa canal, the Delta Cross channel and the Delta Mendota canal.

The 37-mi. Madera canal was completed in June 1945. Construction work on the 156-mi. Friant Kern from Friant dam to Bakersfield, Calif., was started in Aug. 1945. These two large gravity canals were designed to carry water from Millerton lake, storage reservoir created by Friant dam, to the fertile San Joaquin valley. The first water was delivered through the Madera canal in 1944, with a capacity of 1,000 sec.-ft. The Friant-Kern canal was designed for a capacity of 4,000 sec.-ft.

The 47-mi. Contra Costa canal was almost completed in 1946. Industries in the Antioch-Pittsburg area of the Delta region of Central valley were provided with water by means of this system during 1944. The canal had a capacity of 350 cu.ft. of water per second.

The 120-mi. Delta Mendota canal, with a diversion capacity of 4,600 sec.-ft., was planned to transport the

water along the west side of the San Joaquin valley to Mendota pool. Initial construction was a 12.9-mi. section near Patterson, Calif. The 50-mi. Delta Cross channel was scheduled for construction on the Central valley project, with 8,000 to 10,000 sec.-ft. diversion capacity, to carry Sacramento river water to the San Joaquin river.

In the decade 1937-46 the bureau of reclamation built 591 mi. of canals. Under construction at the end of the decade were several large tunnels and canals designed for the irrigation systems of the Columbia basin project (Washington). These vast waterways would ultimately transport water stored by Grand Coulee dam to 1,000,000 ac. of land.

The 2-mi. Bacon tunnel and the 1,020 ft. Bacon siphon, both 23 ft. in diameter, were under construction in 1946. Work was also progressing on sections of the Columbia basin main canal, with a carrying capacity of 9,700 sec.-ft. of water. The portions of the canal under construction varied in width from 95 ft. to 200 ft. at the top of embankments and were from 20 ft. to 48 ft. deep. This work was located between Grand Coulee dam and Ephrata in central Washington.

World Developments.—The continued advance in tunnel-driving methods, through improved mechanization, accelerated new developments in aqueduct design during the decade. Formerly, mountain obstacles were circumvented by longer pipe lines, or channels, where later the direct route by tunnel was not only feasible, but also more economical, provided that the desired cross section for water carriage was large enough to satisfy the economic requirements of tunnel driving (i.e., in hard rock, not less than 8 ft. wide by 6 ft. high, or, in soft materials, such as clay, *7 ft. diameter.)

Tests clearly showed the advantage of lining rock tunnels with concrete, to reduce frictional losses and thus enable tunnels and channels to be constructed with small gradients of as little as 1 in 3,000. An aqueduct of this gradient, and with a water section of 50 sq.ft., could deliver more than 100,000,000 U.S. gal. per day, compared with less than 50% of this flow for a similar, but unlined tunnel. Prior to 1939, German engineers experimented with permanent smooth synthetic linings of the vinyl resin group, but concrete, poured in situ against removable steel shuttering, had yet to find an economic rival. The Mardale tunnel, five mi. long, of the Manchester (England) Haweswater scheme, was a first-class example of an efficient concrete lining, the surface being glasssmooth. For gravity-flow tunnels, built through durable rock, some economy of construction was effected by omitting the normal, but highly expensive roof lining (with which the water was not in contact). For the transport of acid waters from peat-bearing gathering areas, or through sulphate-bearing rocks, aluminous cement-concrete was used, to inhibit attack, which could eventually weaken ordinary concrete linings, increase its surface rugosity and thereby reduce its efficiency. Following the damage to the unreinforced concrete lining caused by water pressure of 540 ft. head during the final test of the Sydney pressure tunnel some engineers returned to the conservative policy of limiting pressure tunnels to those areas where the imaginary free earth pressure above the tunnel was at least equal to the water pressure within the tunnel. This assumption, however safe, ignored the great variety in geology that the resistance of a large number of hard rocks to rupture is many times their superincumbent load, while, beyond a certain depth in some clays (e.g., London, Eng.), their equivalent fluid pressures remain constant, irrespective of their distance below the surface.

The location of aqueducts, through improved site investigation, both geological and geophysical, merited more attention than before in the years 1937–46; in the Lochaber (Scotland) scheme of 1937 a 15-mi. tunnel was preferred to a shorter, straight tunnel, in order to follow an angular course within the mountain, parallel to the nearest surface contour, both to facilitate construction, via many short adits (i.e., horizontal branch tunnels to the surface) and to collect water from neighbouring streams. This procedure was then considered in water supply practice, in order to supply intermediate towns which would normally be separated from a straight aqueduct in tunnel by the intervening lateral obstacle of mountain.

Channels.—Aqueducts in channel, constructed at a flat gradient consistent with obtaining an economical section, are confined to situations where the normal fall of the ground has a gradient similar to that required for the intended water flow. Otherwise, in water supply, where water itself is more prized than its potential energy, covered channels were more common than in hydroelectric development, both for pollution protection, their reduced risks of failure in operation and reduced losses through leakage, compared with pressure aqueducts. At Umtali in Rhodesia great economy was claimed in the use of precast concrete channels; at Lashkar city, Gwalior, India, "gunite" lining was used.

Pipe Lines.—Pressure pipe lines, though more costly than channels, are of more numerous variety, in cast iron, steel, reinforced concrete and prestressed concrete. Cast iron, the traditional material, was subject to internal corrosion which rapidly reduced its effective flow capacity. The increased rugosity of the pipe lining was the principal cause of the reduction in flow. Some unprotected cast iron pipe lines had, however, been in operation more, than 100 years, made possible by regular rehabilitation. Thin concrete linings up to 1 in. thickness to cast iron pipes re-popularized this metal for mains up to 48 in. diameter. Operational pressures were extended beyond 800 ft. head by the occasional use of high duty metal of superior strength, but, normally, beyond this limit, steel had to be used.

Steel pipes, protected with bitumen lining and protective wrapping, were the subject of conflicting expert opinion as to the long-term efficacy of the bitumen protection which, in some cases, suffered embrittlement with age, thereby exposing the metal to rapid attack. Early examples, however, of unprotected steel mains had given more than 40 years' service before requiring replacement. For high-pressure operations, more common to hydroelectric development, steel, owing to its greater strength, was the only possible medium, but, in practice, it was frequently limited by welding technique to 1 in. metal thickness. For low-pressure work, the earliest tendency to employ thin shells of metal thickness less than onehundredth of the diameter gave way to thicker shells, or stiffening by internal concrete linings, through the knowledge that corrosion was accentuated by flexing of thin plates. Moreover, it was found that corrosion intensified at the bottom of the pipe, where the trench in which it rested tended to act as a natural drain. In Australia, where 23 mi. of 68 in. diameter aqueduct were being laid in 1946 for the Victoria water supply from Sylvan dam, steel was generally preferred. In South Africa, by way of comparison, this preference appeared to be less marked,

cast iron being employed at all submerged river-crossings, where corrosion was likely to be more intense than elsewhere. As an alternative to bitumen lining, concrete linings to steel tubes were used by many authorities, but one (Capetown, South Africa), had to undergo scraping to remove internal growths. The highest recorded waterhead on any aqueduct remained at about 5,700 ft. on the welded steel pipe line of the Rhône hydroelectric scheme. For medium heads, an advance on this practice was the adoption of thin steel shells, reinforced with a helix of steel bar, encased in concrete. Originally, this was featured in the "Bonna" pipe, commonly used in Europe, but only in later years was a satisfactory joint developed. With low-pressure aqueducts, where the waterhead does not exceed about 150 ft., reinforced concrete was the medium, but it was seldom possible to utilize the steel economically because, even at low stress, the surrounding concrete tended to crack. On large diameter pipe lines, where the internal pressure varied considerably between the top and bottom of the pipe, the economic section adopted was that of a flattened circle, so proportioned as to produce uniform circumferential stress, as in the Galloway (Scotland) hydroelectrical development of 1938. Such stress analysis is similar to the determination of the shape of a drop of water supported on a horizontal plane.

Extensive research was undertaken on prestressed concrete pipes, which originated in France and which comprised a concrete shell, compressed circumferentially by a coil of steel wire within the concrete, in a similar manner to the prestressing of early gunbarrels. Owing to the higher working stress of hard-drawn wire compared with steel (80,000 lb. per sq.in. as against 18,000 lb. per sq.in.) the quantity of metal required was only about one-fifth that of mild steel. The prestressing was so adjusted that the concrete shell remained in compression when the pipe was under internal pressure, thus preventing both fracture of the concrete and the exposure of the reinforcement to corrosion. This type of pipe line was expected to rival existing types for diameters greater than 24 in., and, in particular, for those operating under medium pressure.

Operation.—Operational considerations forced detailed attention to the charging of pressure aqueducts and the proper placing and sufficiency of improved types of air valves at summits and along rising gradients, to expedite the removal of air. To facilitate the dewatering and recharging of these aqueducts many authorities insisted on the complete elimination of level grades where both water and air might collect, and the provision of more inspection manholes at intervals, in some cases of 1,000 ft. In Europe probably more than elsewhere, when new aqueduct construction ceased during World War II, other ways had to be found to increase the efficiency of existing works. This brought about a relatively new study of the problem of economic operation toward higher flow capacities. For the renewal of peat deposit which restricted flows, brush-scraping, which did not expose the metal to attack, proved in some instances so efficient that it became a yearly practice.

In long aqueducts, consisting of many gravity and pressure parts, restrictions on one section were overcome to raise the flow of the whole. But it was generally found that aqueduct design in the past had not allowed sufficiently for the peak load which was required on occasions. From this water supply experience, certain facts emerged: that the flexibility of peacetime operation generally demanded either a potential capacity at least 50%

greater than the calculated mean supply from the reservoir, or the provision of potential means for mechanically boosting the flow.

In some countries afflicted by World War II, the advantage of standard pipes and fittings, where possible, for aqueducts was more obvious than elsewhere. The metropolitan water board (London) wisely planned new development in twin 48 in. pipes, to be laid at 20-year intervals along different routes, and interchangeable with existing stock, in place of the original program of a single nonstandard, but larger diameter line.

Although the traditional method of crossing rivers still remained popular, either by a pressure aqueduct below the bed of a river (where it was difficult to dewater and repair the aqueduct) or by a pipe supported on a bridge, self-supporting pipe-bridges, principally in steel with welded joints, were also developed. Their greater economy lay in the redundancy of the independent bridge to support the pipes which, if suitably designed, were capable of supporting themselves. The additional thickness of steel required to bridge quite large spans was of small cost, and the reduction in size of foundations and abutments was proved economic in low-bearing soils. A multiple-span bridge of 48 in. diameter, operating at 500 ft. head, and up to 90 ft. spans, required only an additional metal thickness of about 1/4 in. Self-supporting pipe arch bridges were also constructed in cast iron, but the air valve at the crown, their angular shape, difficulty of access and lack of structural beauty retarded their development. The long but small diameter catenary bridge in Japan, where the wire rope carried the contiguous pipe-load, was further indication of possible future development. Arabia

A peninsula of c. 923,600 sq.mi., with an estimated pop. of 10,084,000, Arabia consists politically of two independent Arab states (Saudi Arabia and Yemen), of the nominally independent sultanate of Oman and Muscat (Masqat), of the territories of Trucial Sheikhdoms of Oman and Qatar (British protectorates), of a nominally independent sheikhdom of Kuwait and of the colony and protectorate of Aden (q.v.).

Saudi Arabia.—An independent kingdom formed by the union of the Sultanate of Nejd and of the kingdom of

President Roosevelt en route from the Yalta conference, entertained King Ibn Sa'ud aboard a U.S. destroyer in Great Bitter lake near Cairo, Feb. 20, 1945. The king's 800-mile journey marked a first departure from Arabian soil

Hejaz under the Ibn Sa'ud dynasty (1926) and by the incorporation of the former principality of Asir (1934). Respective areas: Nejd 413,800 sq.mi.; Hejaz 182,200 sq.mi.; Asir 13,900 sq.mi.; total 609,900 sq.mi., about 66% of the Arabian peninsula. The population of Nejd (no census taken) was estimated at 3,000,000, that of Hejaz at 1,500,000 and that of Asir at 750,000; total 5,250,000 (about 52% of the population of the peninsula). The people are Bedouin nomads in transition to the civic life of communal organization; they speak Arabic and are ardent Mohammedans still under the influence of the Wahhabi revival of 1913–26. Saudi Arabia had still two capitals: one in Hejaz–Mecca (pop. 80,000) and another in Nejd–Riyadh (30,000). Other chief towns: Jidda (40,000), Medina (30,000), Hofuf (30,000) and Sabiya (capital of Asir, 20,000).

The ruler of Saudi Arabia throughout the decade 1937—46 was Abdul-Aziz ibn Abdurrahman al-Faisal al-Sa'ud (b. 1880) who in 1927 assumed the title of "King of the Hejaz and of Nejd and its dependencies." Eldest of the king's 32 sons, Emir Sa'ud (b. 1905), who was formally declared heir apparent on June 15, 1933, resided in Nejd and exercised there the functions of viceroy. The second son, Emir Faisal (b. 1907), acted as viceroy in Hejaz in his father's absence; according to the constitution issued on Aug. 29, 1926, he also presided over a council of ministers and acted, as the foreign minister of the kingdom.

The frontiers of Saudi Arabia were more or less defined with Iraq, Kuwait and Trans-Jordan in the north and with Yemen in the south; Ibn Sa'ud, however, did not recognize the annexation of Aqaba and Ma'an to Trans-Jordan. They were rather indefinite with the territory of the Trucial Sheikhs of Oman and with the sultanate of Oman and Muscat in the west and with the Aden protectorate in the south; but that part of Saudi Arabia is the uninhabited desert of Rub' al Khali. (X.)

* * *

The kingdom of Saudi Arabia, constituted in 1933 by

the union of the two kingdoms of the Hejaz and Nejd under the single banner of the house of Sa'ud, was indeed fortunate in that, during the period immediately preceding the decade of world-wide tragedy covered by this review, it was able to prepare for the coming storm by the effective stabilization of its economic and political foundations with the result that, by the grace of God and with the help of old and new friends in Great Britain and the United States of America, Arabia not only came unscathed out of the furnace of war but actually prospered greatly in the midst of almost universal havoc and desolation.

In the year 1933, the succession to the throne of Saudi Arabia was formally secured by the public acclamation of H.R.H. the Emir Sa'ud as crown prince and heir apparent. In the same year a concession was granted by the government to the Standard Oil Company of California for the exploration and exploitation of the oil resources of the eastern provinces of the kingdom, while at about the same time a similar concession was negotiated with an Anglo-American syndicate for the development of an ancient gold mine at Mahd al Dhahab in the Hejaz mountains. The following year witnessed the final settlement, after a brief but successful campaign, of a long drawn-out frontier dispute between the sister kingdoms of Saudi Arabia and the Yemen, whose political relations were placed on a satisfactory basis of friendship by the delimitation and demarcation of a mutually acceptable boundary.

The relations of Saudi Arabia with its neighbours were further improved in 1936 by the inception of full diplomatic relations with the kingdom of Egypt with the now obsolete ceremony of the "holy carpet," which in former times used to accompany the Egyptian pilgrimage to Mecca. The resumption of friendly relations resulted immediately in the generous co-operation of the Egyptian government with the government of Saudi Arabia in a number of beneficial schemes for the improvement of the amenities of the holy land of the Hejaz, including muchneeded repairs to the prophet's mosque at Medina and the improvement of the pilgrim road from Jidda to Mecca and 'Arafāt. In the following years, the two governments further co-operated in the survey and realignment of the

road from Jidda to Medina, and also in the consideration of various schemes for the re-organization of the water supply and lighting systems of Mecca. And the cordial relations between the two countries were finally consummated in 1945 and 1946 by an exchange of state visits by their monarchs, which captured the public imagination of all the countries of the Arab world and did much to reinforce the spirit of unity and co-operation which had already, in 1945, served to draw the Arab countries closer together within the framework of the Arab league (q.v.).

With the stabilization of the economic and political situation in Saudi Arabia and, above all, the actual discovery of oil at Dhahran and the gold-mining operations, the country seemed well set for a long period of uninterrupted prosperity and progress when, in 1939, the outbreak of World War II and the consequent restriction of shipping facilities to the Arabian ports seemed to presage a period of stagnation, if not disaster, in a land so largely dependent on the import of many essential commodities, including foodstuffs and piece goods, motor vehicles and machinery. At the same time the pilgrim traffic, which had hitherto been the principal source of the country's revenue, began to decline and later came to a complete stop owing to the entry of Italy into the war and the consequent dangers of navigation in the Red sea area. Furthermore, the Allied Powers had found it necessary to impose severe limitations on the production of oil in the middle east with the result that the promising progress already made in actual production in the Hasa province had to be suspended until the last year of the war, when production was resumed on a satisfactory basis. It is sufficient to say that, as compared with about 30,000 tons of oil in 1939, no less than 3,000,000 tons were produced in 1945, while the estimate for production in 1946 was more than double that figure and still further increases were anticipated as the result of arrangements negotiated during the war years for the construction of a 1,200-mi. pipe line from the Hasa oil fields to the Mediterranean.

On the outbreak of war in 1939, the Saudi Arabian government adopted an attitude of de facto neutrality but refrained from making any formal announcement on the subject. At the same time it maintained a friendly and sympathetic attitude toward the Allied cause, while Britain and, later, the United States cordially reciprocated that attitude by making substantial contributions toward the maintenance of economic stability in Saudi Arabia, whose principal sources of revenue had been completely cut off by Allied wartime policy. By these means, and owing to the foresight shown by the Arabian government in laying in considerable stocks of all necessary commodities before the war, the economic crisis was successfully tided over until the Allied victories, first over Italy and later over the other axis powers, enabled the country to resume its longinterrupted progress under more normal conditions.

Meanwhile the Saudi Arabian government had to cope with a somewhat complicated political situation arising out of war conditions. The German minister, who happened to be absent from Jidda at the outbreak of war, was not encouraged to return; and German interests were looked after by the Italian legation until the entry of Italy into the war. For some time after this event the Italian legation continued to function, but circumstances ultimately compelled it to close down; and the Italian community at Jidda was segregated in its own interests in one of the quarantine islands. The crews of some Italian destroyers which were compelled to take refuge in Arabian terri-

torial waters were duly interned on the island of Jaziva Sa'd, whence the sick were transferred to a camp near Taif. A further complication was provided by the French legation, where the minister remained faithful to the Vichy government until the end, while after the Allied capture of Syria a Free French representative of ministerial rank was permitted to take up residence at Jidda in the interests of General de Gaulle.

The interest of the United States in Arabian oil and the subsequent entry of that country into the war as a principal Allied Power resulted naturally in the expansion of American diplomatic and other contacts with the Saudi Arabian government. These contacts led progressively to the conception of a number of important enterprises in connection with agricultural and economic development. Many deep wells were bored in the desert to improve the country's water supply, while a team of expert farmers from Arizona in due course came in to supervise a spectacular and successful agricultural experiment in the Kharj province, where several thousands of acres of desert were brought under cultivation to supply Riyadh, the capital, with vegetables and grain. The country also benefited greatly by its inclusion within the scope of the Allied Lend-Lease program, with the result that by the time the war came to an end Saudi Arabia was in the fortunate position of finding itself in almost as favourable economic and administrative circumstances as it would have achieved in the normal course of the development planned before the war, had those plans not been interrupted by events over which the government had no control. Inevitably, owing to the difficulty of securing supplies from abroad in adequate quantities, the prices of all commodities tended to rise steeply to the disadvantage of the poorer classes; and their position was still further worsened by the seasonal recurrence of a locust epidemic during the years 1944 to 1946. A mission sent to Arabia by the International Locust commission failed to check this epidemic because of a lack of necessary equipment and of experience of local conditions.

The resultant problems of scarcity and high prices, however, were tackled resolutely by the government, which promptly issued a free bread ration to the whole population of Mecca, Medina and other towns, while an extensive development program was undertaken to procure work and wages for the agricultural population rendered unemployed by the ravages of the locusts. Moreover, the government made arrangements to ensure the requirements of consumers in the matter of foodstuffs until the war crisis ended; and the country was perhaps in a more prosperous condition than its neighbours.

By way of reciprocation for the material assistance rendered to the country by the Allies the Saudi Arabian government helped the Allied cause substantially by exercising a pacific and restraining influence in the whole Arab world and by counselling patience amid the difficulties and troubles which beset many of the Arab countries during this period, particularly in Palestine and in Iraq and Syria; both the latter had the misfortune of being caught in the vortex of war. At the same time, the Saudi Arabian government played a prominent part in championing the aspirations of all the neighbouring Arab countries toward independence, while its adhesion to the project of an Arab league substantially increased the prestige of that institution when it was ultimately formed in March 1945.

The important part played by the Saudi Arabian government in the middle east during the critical years of the war received formal recognition in Britain and the United States when those two powers invited it and the other

Arab states to declare war on Germany and thus be able to be represented at the San Francisco conference. All these states in due course became original members of the United Nations. But this development had been preceded in Feb. 1945 by a visit by H.M. the king of Saudi Arabia to Egyptian territory and his historic meetings with President Roosevelt and Prime Minister Churchill, with both of whom all the problems of the Arab world were discussed in an atmosphere of cordiality and good will. It was on this occasion that Churchill greeted his majesty as one who had proved himself a good friend in time of need to Britain and its Allies, while Roosevelt gave through his majesty to the Arab world a solemn assurance that the Arab attitude towards the Palestine problem would receive the sympathetic support of the United States government. The sudden death of the president only a month after this meeting was therefore widely regarded by the Arab peoples everywhere as a grave blow to their essential interests; but the relations of Saudi Arabia with its two great Allies continued to be cordial in the extreme. During the postwar period, the Arabian government continued, in spite of certain disappointing developments in the international field and particularly in the middle east, to show its confidence in the Great Powers by practising and counselling restraint and patience pending the consideration and settlement of all the political problems involved.

Meanwhile, the Saudi Arabian government faced the immediate future with confidence in the knowledge that in a world at peace, its own economic resources would be sufficient to guarantee the accomplishment of the many schemes of development which had been planned in detail during the war years when circumstances made it impossible to proceed with their execution. The resumption of the Meccan pilgrimage and the development of the country's oil resources promised to ensure financial stability, while the comprehensive review and revision undertaken during 1946 of the administrative and fiscal system of Saudi Arabia would enable the government to make the best and most economical use of its ever-increasing resources for the benefit of all the people committed to its charge. The government continued to play its proper part in international affairs as a member of the United Nations and a member of the Arab league. (I. Sp.)

Yemen.—An independent kingdom in the southwestern corner of the Arabian peninsula. Area: c. 75,000 sq.mi.; pop. (estimate): 3,500,000. Chief towns: San'a (capital) (25.000), Hodeida (15,000). In the north the boundary between Yemen and Saudi Arabia was defined by the treaty of May 20, 1934. In the south the boundary between Yemen and the Aden protectorate was fixed by the Treaty of San'a of Feb. 11, 1934. Ruler: King Zaidi Imam Yahya ben Muhammed ben Hamid ed Din.

Oman and Muscat.—A nominally independent sultanate situated in the eastern corner of the Arabian peninsula. Area: c. 82,000 sq.mi.; pop.: (1937 est.) 500,000, mainly Arabs, but there is a strong infusion of Negro blood. Chief towns: Muscat or Masqat (capital) (4,200), Matrah (8,500). Ruler: Sultan Sayyid Sa'id ibn-Taimur.

Trucial Sheikhdoms.—A galaxy of eight small Arab states extending from Khor Khalba, on the Gulf of Oman (90 mi. S. of Ras Musandam) to a point about 50 mi. W. of Qatar peninsula in the Persian gulf. Area: c. 41,800 sq.mi.; pop.: 120,000. Under the treaty of March 1892 (Nov. 1916 in the case of Qatar) the sheikhs, on behalf of themselves, their heirs and successors, undertook that they would on no account enter into any agreement or correspondence with any power other than Great Britain.

Kuwait.-A nominally independent sheikhdom on the

coast of the Persian gulf between the territories of Saudi Arabia and Iraq. Area: 1,930 sq.mi.; pop.: 50,000. Ruler: Sheikh Ahmad ibn-Jabir as-Subah.

Arab League

The Arabs, one of the oldest races in the world, are distinguished by having permanently influenced the history and development of the near and middle east for more than 4,000 years.

Arabization.—Before the Christian era the Arabs were steadily infiltrating into the fertile crescent and the Nile valley, as settlers, traders, graziers, raiders and invading conquerors. All ancient builders of civilization in Babylon, Egypt, Nineveh, Damascus, Palmyra, Patras, Phoenicia (Tyre) and Carthage, had close racial and linguistic affinities with the original Arab stock. These affinities between the nomadic Arabs and their kin—Assyrians, Chaldeans, Arameans, Phoenicians, Carthaginians, Hyksos, Hebrews and others—must be borne in mind in considering the Arabization of a vast territory embracing western Asia and north and east Africa—the actual domain of the Arab league.

The modern Arab is the product of this continuous fusion and assimilation of related races with successive waves of emigrant Arabs resulting from the great religious, cultural and political Arab movement of the 7th century.

Under the inspiration of the Prophet Mohammed, the Arabs became united and, under the banner of Islam, carried their mission in every direction with unprecedented success. Before Mohammed, Arab unity was nonexistent. The Arab social and political structure was based on tribal patriotism. The Arab prophet and his ideas, recorded in the sacred Koran and the Hadith, transformed Arab society from a basis of fratricide clans and feudal states into a fraternal, broad-minded, tolerant international society capable of dominating vast areas from China to France during many centuries and successfully linking the older Greek and Roman civilizations with western ideas and culture. The golden era of Arab rule in the east and west, remarkable for its stimulating progress in many spheres, left behind an imperishable legacy in literature, architecture, science and the arts as well as a great Arab nation stretching from the Indian ocean to the Atlantic.

Movement for Unity.—The modern movement that produced the Arab league was a new phase in the annals of this ancient people. After the fall of their empires the Arabs had aspired to federation. Sharply conscious of the blessings of unity, they constantly manifested their

Arab league officials meeting at Bludan, Syria, in 1946, reaffirmed their opposition to further immigration into Palestine. The league was formed in 1945

aspirations in revolts, literature, songs, mass meetings, demonstrations and political action.

The beginning of the decade 1937–46 witnessed the inauguration of a number of pan-Arab organizations. These included the Inter-Parliamentary Arab conference (Cairo), Oct. 15, 1938, the Arab Students' conference (Cairo), Nov. 6, 1938, the Arab Women's conference on Palestine (Cairo), Oct. 15, 1938, and the Arab Medical conference (Baghdad), Feb. 9, 1938. Similar conferences, arranged regularly under the auspices of official bodies, continued to bring together Arab engineers, lawyers, pharmacists and members of other professions.

The inauguration of these pan-Arab international gatherings helped lay the foundations for the Arab league, comprising the seven states of Egypt, Iraq, Syria, Lebanon, Saudi Arabia, Trans-Jordan and Yemen.

The London Conference on Palestine, which opened at St. James's palace, Feb. 7, 1939, was a notable landmark. For the first time in modern Arab history, the independent Arab states participated in an international gathering as a united body, recognized as such.

Warring Powers and Arab Unity.—The outbreak of World War II quickened the powerful axis radio campaign aimed at securing Arab goodwill by declarations in support of Arab unity and independence. The dangerous possibilities of this campaign were quickly recognized by Great Britain. British sympathy toward the Arab renaissance had proved an important military factor in World War I. Now, again, Britain demonstrated her realization of the value of Arab friendship. Foreign Secretary Anthony Eden, in his momentous Mansion House speech, pledged Britain's full support for any Arab scheme to secure a greater degree of Arab unity:

The Arab World has made great strides since the settlement reached at the end of the last war and many Arab thinkers desire, for the Arab peoples, a greater degree of unity than they now enjoy. In reaching out towards this unity they hope for our support. No such appeal from our friends should go unanswered. It seems to me both natural and right that the cultural and economic ties, too, should be strengthened. His

Majesty's Government, for their part, will give their full support to any scheme that commands general approval.

First Arab reaction to the competing British and axis offers was noncommittal. Arab faith in imperialist fascist Italy was weak. Italy's mare nostium policy was suspect. On the other hand, Arab experience with Britain and France discouraged any enthusiastic reaction to Eden's declaration. Promises made to the Arabs in World War I had not been honoured. The outcome and effects of British and French policy at Versailles regarding Palestine, Syria, Lebanon and Iraq had caused disappointment in the Arab world.

In the absence of a positive Arab reaction, Britain renewed her approach in the form of a declaration by Anthony Eden, made in the house of commons on Feb. 24, 1943.

As I have already made plain, the British Government would view with sympathy any movement among the Arabs to promote economic, cultural or political unity, but clearly the initiative in any scheme would have to come from the Arabs themselves. So far as I am aware no such scheme which commands general approval has yet been worked out.

Beginnings of the League.—Arab governments and outstanding Arab personalities now responded and proposed an Arab conference. The Egyptian government formally took the initiative, and after long consultations between Arab states the Alexandria protocol was signed on Oct. 8, 1944, laying the foundations of the Arab league.

Saudi Arabia and Yemen at first declined to sign the protocol. King Farouk I of Egypt, accompanied by Abdul Rahman Azzam Pasha, later secretary-general of the Arab league, visited Saudi Arabia for the famous meeting of the two kings at Radwa, in Hejaz, following which the adhesion of Saudi Arabia and the Yemen was secured. Thenceforward King Farouk threw all his influence into the swift creation of the Arab bloc. In Feb. 1945 the official delegates of the seven Arab states met in Cairo to negotiate and sign a pact binding them in an Arab league. It was signed on March 22, 1945, amid the acclamation of the whole Arab world. An official celebration was held at Zafaran palace, Cairo.

Nonrigid Pact.—The pact was elastic in form, affording the signatory states full discretion to accept or reject any majority decision. That provision (originally severely criticized) proved in practice to be a source of strength rather than weakness. The will for federal unity proved to be in advance of the letter of the pact, and Arab public opinion, similarly, was ahead of the Arab governments. The elasticity of the pact helped achieve the peoples' aspirations without friction, and the league itself developed as the British constitution developed—unwritten, yet formidable, adaptable, permanent and capable of continuous extension.

The league pact paved the way for the member states to develop and interrelate their culture. economy and social exchanges for their common good.

In the first ordinary meeting of the league council (Nov. 27, 1945), a cultural treaty was introduced providing the basis for common education and embracing a wide degree of collaboration in science, art, museums, literature, text-books, educational organizations and institutions.

Although the pact did not constitute a defensive alliance, the events occurring in Syria and Lebanon in May-June 1945 demonstrated the Arab states' willingness to accept responsibilities for mutual support which, in practice, amounted to the strongest obligations of mutual defense.

In the international field the league became an instrument of peace. War between member states became absolutely illegal and forbidden under all circumstances. Disputes had to be settled by arbitration. As a peaceful, co-operative institution serving the Arab world, the league extended its services to wider spheres and mediated, for example, in differences arising between Saudi Arabia and Iran. It declared its willingness to affiliate with comparable international bodies, especially the United Nations. Although the league preceded the United Nations, its pact (article 3) provided for full international co-operation with appropriate institutions in politics, economics and social affairs.

The league organization comprized three bodies: (1) the council (in which all member states were equally represented); (2) the secretariat, an administrative and diplomatic agency; and (3) the committees covering culture, economy, legal questions, agriculture, commerce, transport, social affairs, etc. These committees were organized to produce drafts for treaties, agreements or recommendations to be implemented by the council which were to become binding upon all member states electing to adhere to them.

The league's activities were not restricted to member states. The council was charged by Annex II with guarding the interests of all Arab countries and communities not then members of the league; with encouraging their development and eventual independence.

Arab countries automatically were to become eligible for full membership on attaining independence. Although unrepresented in the council, they could be represented in all committees by council nomination. Thus the league rallied Arab forces for freedom and self-determination, and for economic, cultural and social co-operation throughout the Arab-speaking world. The Spanish zone in Morocco (with the approval of the Spanish government) sent delegations to various committees. It was hoped that Britain and France would follow this lead, thus eventually securing representation for every Arab country irrespective of its political status.

Palestine.—Palestine, though it remained a nonindependent country, was nominally represented in the council,

as provided in Annex I on Palestine. Yet 20,000,000 Arabs in Tunisia, Algeria, Morocco and Tripoli could not be represented in the council and had to limit their participation to committees, pending their attainment of complete independence.

The Palestine issue, virtually a clash between the aspirations of two differing races and religions, absorbed and diverted an enormous proportion of the energies of the league making, out of Palestine's special circumstances, an exceptional case.

League's Mission.—The Arab league's mission and purpose were clearly expressed in the text of the pact, the council's resolutions, the committee meetings of Arab foreign ministers and the public declarations of the league's secretary-general. It excluded racial discrimination by its formal definition of an "Arab" as "one who settles in Arab countries, speaks Arab language and shares Arab sentiment." His racial origin, whether Nordic or Mongolian, was immaterial.

Other tenets of the league were: (1) complete religious tolerance; Christians, Jews, Moslems and others were conceived of as absolutely equal citizens in an Arab state, enjoying the assured right to practise their faith freely; (2) freedom, equality and self-determination for all people, irrespective of race, creed or colour; (3) denunciation of war, for whatever reason, as unjustifiable; peace was the permanent objective; (4) co-operation in a free world, thrown open and developed for the common welfare of mankind; (5) complete support for all international institutions devoted to establishing permanent peace and world justice.

The Arab league, backed by the individual Arab states and the public opinion of 70,000,000 Arab-speaking people, stood for these basic principles. By their unanimous resolution at Alexandria (Aug. 13, 1946) the Arab states foreign ministers pledged Arab support in all just causes brought before United Nations, irrespective of other circumstances.

Arce y Ochotorena, Emanuel

Cardinal Arce y Ochotorena (1879-), Spanish prelate, was born Aug. 18, 1879, in Ororbia, Navarre province. Educated in the Pamplona and Zaragoza seminaries and at the Gregorian university in Rome, he was named bishop of Zamora in 1929 and headed this see during the difficult years of the republic. He specialized in labour and social problems. Mgr. Arce was largely instrumental in developing the Catholic Action in the archdiocese of Tarragona. He was transferred from Zamora to the diocese of Oviedo in 1929, where he supervised the reconstruction of damaged or destroyed churches in the Asturias region. At the same time he served as apostolic administrator of his former diocese. He was elevated to the metropolitan see of Tarragona in 1944 and was created

and proclaimed a cardinal at the consistory in Rome, Feb. 18, 1946. Cardinal Arce y Ochotorena wrote several books on canon law and various pastorals dealing with dogma and morals.

Archaeology

Six full years of the period covered by this résumé (1937-46) were war years; during this time there were naturally few full scale archaeological excavations. Moreover, the world economic depression of the earlier 1930s had somewhat curtailed interested donors, and the number of expeditions in the field in 1937-39 was less than in the earlier '30s. The unfavourable conditions set for excavators by some foreign countries also contributed to this slackening of activity.

Eastern Hemisphere

The fascination of ancient Egypt and Greece for the lay public and for museums made it almost always possible to stimulate at least some interest and financial support for work in those countries regardless of the fact that the excavator has no claim on any share of the antiquities he uncovers. No other regions can claim such popular interest, however, and restrictive antiquities laws have the effect of discouraging excavators, unless some fair portion of their antiquities may be returned to their supporting institutions. Another consequence, apparently not realized by regimes whose laws discourage competent excavators, is that avaricious and destructive illicit antiquities dealers flourish. Nevertheless, the wave of emotional nationalism which swept the world in the 1930s was in some cases reflected in the application of restrictive laws, and in fewer expeditions.

It must also be said that a number of the campaigns on larger sites which began in the '20s or early '30s were finished, and excavators looking for new sites were also cautious because of their apprehension over the general world unrest.

As World War II began, planned excavations were generally terminated. Some planned activities continued dur-

"Throne of Solomon," a fortress in northwestern Iran, as seen from the air by members of the 1935–37 expedition of the Oriental Institute of Chicago. This photograph appeared in Flights over

ing the period of the "phony war" (Sept. 1939-April 1940), but most of the wartime discoveries were made as results of accident. The brilliant exception to this was the record achieved by the enlightened Directorate of Antiquities in Iraq, with its spectacular success in exposing materials from almost the whole range of that country's history. Nor would the work of the Turkish archaeologists during wartime be forgotten.

In countries actually engaged in the war, the enforced pause which might have been used for catching up on the publication of results and for taking stock was only partially effective in this sense, as most of the professional personnel became actively engaged in the war.

Both the western Allies and the Russians had effective teams of archaeologists working in conjunction with their armies; these teams did yeoman service in keeping damage to archaeological museums, collections, surface monuments and libraries down to the minimum possible.

Laws and Methods.—The maturing of local governments in their methodological and scientific care of their own antiquities was not always an easy process. For example, in the Egyptian Service of Antiquities the search for an Egyptian who might be governmental director of archaeological work came to a halt when the Egyptian archaeologist who had been groomed for such work stepped out of the service under clouded circumstances. This left the service under the supervision of a Frenchman, following out a long tradition. Under conditions of an emotional patriotism in Egypt, such a situation was not a happy one and did not make for stability of the government agency of greatest influence for the development of archaeology and the preservation of monuments.

One of the most distressing episodes lay in the widespread damage done to the Theban tombs, from which pieces were removed for illicit sale. Between 1937 and 1942 about 40 guarded tombs were so attacked before the Egyptian government took action to tighten the guard system and to expropriate the Theban necropolis. In 1946 a model village was being constructed for those Egyptians living in the necropolis; eventually they were to be moved away from the area of temptation.

The effects of the various antiquities laws, either to restrict or encourage competent excavation, have already been suggested. Several important conferences were held which concerned themselves, at least in part, with the

establishment of mutually fair antiquities laws. The Cairo conference, called in 1937, under the auspices of the Institut International de Coopération Intellectuelle and sponsored by the League of Nations, made some valuable suggestions. Further understanding was gained at the unofficial Jerusalem conference of 1943. While the mandatory authorities refused to recognize this conference, its proceedings were on record.

More general conferences were held, especially those of the Institute of Archaeology of the University of London, where the legalistic aspects of excavation were also discussed. Sufficient thought was given to the matter so that recommendations could be made to the United Nations Educational, Scientific and Cultural organization of the general United Nations' organization.

Methodologically, the processes of complete and exact excavation and interpretation of archaeological materials stood to benefit largely from technological advances made during World War II. This was especially true in the case of aerial survey and photography; the status of this method was summarized by J. K. St. Joseph (Geographical Journal, 1945), and an extremely handsome example of the technique was E. F. Schmidt's Flights over Ancient Cities of Iran (1941).

H. Godwin and others continued to perfect methods for the analysis of pollen derived from ancient sites, especially in terms of the use of changing patterns of forest cover as an indication of time change. F. R. Matson pioneered in the microscopic analysis and objective description of the clays from which ancient pottery was made. There was a growing consciousness on the part of field archaeologists of the necessity of conserving the more unspectacular types of objects, and of animal bones, soil samples and other nonartifactual evidence, against the time when tests might be devised to aid in the interpretation of these materials.

Gains.—As this report will show, the great gains of the period 1937–46 were perhaps more in publication than in actual materials excavated. Of the items detailed below, the most important new finds were probably the following:

The fossil neanthropic Swanscombe man associated with flints of Acheulean type, the discovery of the Anyathian chopper-chopping tools of Burma, and the accidental finding of the remarkable cave paintings of the Grotte de Lascaux, highlighted the earlier prehistoric period. For the later prehistoric period, the excavations of Seton Lloyd and Fuad Safar in Iraq stood out, as did the uncovering of the earlier Syro-Cilician village materials at several sites, the clarification of the extent of the Ertebolle in Denmark, and work in neolithic and bronze age horizons in Russia. Excavations in the early historic period yielded important 21st-22nd dynasty and 1st to 2nd dynasty tombs in Egypt, more of the historically significant Mari correspondence in cuneiform, a remarkable cache of tablets at Pylos in Greece, and the spectacular trappings of an early British king in the Sutton Hoo ship burial.

The period also evidenced signs of growing concern with the broader aims of archaeology, that its goal must be far more than the filling of museum shelves, and the esoteric pleasures of its practitioners. In the first article of the new Journal of Near Eastern Studies (1942), J. A. Wilson made a plea for broader and more intelligible interpretations of archaeological materials as a contribution to general understanding. Grahame Clark's admirable popular book, Archaeology and Society (1939), pointed to the dangerous uses to which warped archaeological interpretation was put in the thought-controlled totalitarian countries, and implied that an intelligent public

should know enough of the facts of archaeology to reject dangerous racial and nationalistic interpretations. There was unrest concerning the old style systems of classification (cf. R. J. Braidwood's "Terminology in Prehistory," Human Origins—An Introductory General Course in Anthropology, Selected Reading Series II, the U. of Chgo., (1946), which were held to obscure general understanding. V. Gordon Childe's valuable syntheses, in somewhat historical materialist vein, appeared in the Pelican pocketsized What Happened in History (1942–46), and in his Huxley lecture (Jour. of the Roy. Anthrop. Inst., 1944); Childe's studies were objected to as "too materialistic," but they tended to correct a professional outlook which was not enough so.

Archaeology faced the atomic future with a realization that, since written records could account for less than one one-hundred-thousandth of man's life on this earth, its duty was to recover and make available human experiences and truths learned in that much vaster past. It was rather the role of the humanities and the social sciences generally to see to it that mankind might benefit from knowledge of its past experiences.

As 1937 began, the extent of archaeological knowledge could be said to be summarized in such books as M. C. Burkitt's Old Stone Age, V. Gordon Childe's New Light on the Most Ancient East, and the later volumes of the Cambridge Ancient History. The broad outlines appeared to be set, but subsequent developments were to show that even some of these broad lines were in error. Many voids in the framework were later filled in—with this came the realization of new problems, and a consciousness that various important types of evidence had been slighted, even in the periods which seemed well known. During the decade 1937–46, steps were taken to correct some of the oversights of this nature, and more could be expected in the future.

Fossil Man.—The period was marked by the appearance of some important finds in the field of human palaeontology, and also by the appearance of several monumental reports. These last consisted of F. Weidenreich's Giant Early Man from Java and South China (1945) and The Shull of Sinanthropus Pekinensis (1943); T. D. McCown and A. Keith's The Stone Age of Mt. Carmel, ii (1939); "Report on the Swanscombe Skull" (Jour. of the Roy. Anthrop. Inst., 1938); and W. M. Krogman's "Cranial Types from Alişar Hüyük . . ." (Oriental Inst. Publ., xxx, 1937) and "Racial Types from Tepe Hissar . . ." (Verhandelingen der Koninklijke Nederlandsche Akad. van Metenschappen, xxxix, 2, 1940). C. C. Coon's comprehensive Races of Europe (1939) was a landmark in physical anthropology.

Weidenreich's works took into consideration the newly recovered fossil materials of China and Java, and were important not only in their excellent presentation of materials, but also in that their author struck at "monocentrism," the theory that man (as a culture-bearing, tool-using being) had only one place of origin. According to Weidenreich's polycentric theory, man's early ancestors were scattered throughout a great part of the earth and developed independently in locations selected accidentally. One of the important facets of Weidenreich's position was that Neanderthal man, in Europe as elsewhere, was not exterminated by later types but himself developed into later types.

McCown and Keith's H. palestinensis was already a mixed breed, but these authorities were not inclined to

see direct evolution from neanderthaloid to *H. sapiens* types. New neanderthaloid fossils made their appearance in Tangiers, South Africa, Monte Circeo in Italy and at Teshik Tash and Kiik Koba in Russia.

The remarkable discovery of a very early neanthropic type in a gravel pit near Swanscombe, England, was promptly and fully reported. This *sapiens*-like type was found associated with Acheulean type flints in beds assigned to the second interglacial period.

A human skull was rediscovered in the collections from the site of Chatelperron, apparently pertaining to this earliest west European blade-tool assemblage. Another human fossil, apparently associated with the same general type of artifacts, appeared at Ksar 'Akil, north of Beirut, in Lebanon.

An interesting and presumably Upper Pleistocene human fossil appeared at Keiloi, Australia, but was not fully reported. The exact whereabouts of the original Sinanthropus material from near Peking, China, was now in question—it might have been sunk while in transshipment to the U.S.

The work of W. M. Krogman on the human populations of the ancient near east was of extreme importance, and the Turkish physical anthropologist, M. S. Şenyürek, made valuable additions.

The Early Prehistoric Period: 500,000 to 8,000 B.C.—Several studies appeared after 1937 which were of such breadth as to concern the earlier prehistoric archaeology of the whole eastern hemisphere. Two of these studies were T. T. Paterson's On a World Correlation of the Pleistocene (1941), and "Geology and Early Man" (Nature, 1940), which attempted to bring late geological and archaeological information together in an understandable whole. Paterson's approach to the classification of both human palaeontology and archaeology was essentially monocentric; one of his schemes suggested possible family-genus-species relationships for the various different types of early stone tools.

H. L. Movius' Early Man and Pleistocene Stratigraphy in Southern and Eastern Asia (1944) also had broader implications than its title implied. It was Movius' position that the stone tools of the far east pertain to a tradition (a set of persistent habits in manufacture) not formerly recognized, and completely separate from those of Europe and Africa. This was a basic challenge to science's understanding of early cultural distributions. Previously, it had been assumed that some such scheme as that presented so clearly by Paterson might have held. Movius' new approach, when coupled with Weidenreich's polycentric theories, opened vast new possibilities (and problems) in the attempt to arrive at a general understanding of man's prehistoric past.

Two contributions by the geologist, F. E. Zeuner, The Pleistocene Period (1945) and Dating the Past (1946), were of great importance, although not without controversy. In the latter volume especially, Zeuner also attempted to bring together the important facts of geology and prehistoric archaeology. His attempt at a geochronology, and the means of assessing dates for archaeological materials which it implied, was in part based on the similarities of curves plotted to show geological (especially glacial) phenomena with the curves of variations in the amount of solar radiation received by the earth. While the over-all dates supplied by the Zeuner scheme were commendably conservative, the time durations implied for the last phases of the Ice Age were much longer

than had formerly been suspected.

Three very important contributions to the understanding of prehistoric times in the west appeared in the Papers of the Peabody Museum of Amer. Anthrop. and Ethnol., Harvard Univ. Harper Kelley's "Acheulean Flake Tools" (1937), and T. T. Paterson's "Core, Culture, and Complex in the Old Stone Age" (1945) approached an examination of the real meanings of the existing system of classification of earlier palaeolithic antiquities. D. A. E. Garrod's "The Upper Palaeolithic in the Light of Recent Discovery" (1938) was a landmark; in this synthesis, Miss Garrod suggested the relationships and significance of all of the main groups of archaeological materials of latest Pleistocene times, from the near east to Britain and from the Baltic to Kenya. She insisted that the prehistory of all Europe and beyond need not conform to the classic scheme set in France. Her point of view was underlined by R. Lantier's account (Proceedings, Prehistoric society, 1945) of wartime discoveries in France, which showed ever increasing complexity, local variation and partial contemporaneity of the once classic "Aurignacian, Solutrean, and Magdalenian" materials. It is also interesting that the thesis of Garrod's "The Near East as a Gateway of Prehistoric Migration" (Bulletin, Amer. Schools of Oriental Research, 1937) -for an eastern centre of origin of the blade-tool traditions, with subsequent westward extensions-was later followed in France, as Lantier's remarks on Périgordian origins indicated.

Some important events took place in western Europe in spite of World War II. In 1939, H. Breuil made excavations near Abbeville in the Somme valley in France, and fixed the occurrence of the earliest biface type of flint hand axe, the Chellean, to the Günz-Mindel (or first) Interglacial. Since the material from the type site, Chelles, was not stratified, Breuil's suggestion that the type tool be referred to as "Abbevillian" was generally accepted. At about the same time, T. T. Paterson established a key sequence of earlier ice-age implements at Breckland, in eastern England. The name "Brecklandian" was applied to a variety of flake tools once less specifically included in Breuil's Clactonian, and the area also yielded an Acheulean with a secondary Brecklandian element.

This occurrence of some flake tools with the biface Acheulean tools took place not only in the Breckland sequence and in the materials studied by H. Kelley (see above), but also, among other places, in the Barnfield gravel pit in Kent, England, where the neanthropic Swanscombe skull was found. The importance of this find, associated with flint tools of which some were of standard middle Acheulean type, has already been suggested in the section on fossil man.

Breuil also published (*Proceedings*, Prehistoric society, 1942) a brief opinion on the crude pebble-tool industries of the Atlantic coastal terraces of Portugal. The shell-food collectors who produced this industry were said to have shown remarkably little ingenuity over a vast range of prehistoric time. Breuil suggested calling these industries "Lusitanian," to distinguish them from the more normal artifacts of the interior.

V. Gordon Childe contributed a very important review article in Antiquity (1944) on L. Pericot Garcia's remarkable cave sequence at Parpalló, near the southeast coast of Spain. The following stratified sequence was recovered: Gravettian, Lower, Middle and Upper Solutrean, Solutreo-Gravettian, Magdalenian I-IV. Both this sequence and the artifactual materials contained in it were of great significance to an understanding of the Upper Palaeolithic of western Europe. Formerly, the Solutrean was

supposedly restricted in Spain to the northern part at best. Now it was accounted for not only nearer to Gibraltar, but as an assemblage which included some flaking of 'Sbaïkian type; some excellent tanged points probably developed out of the Aterian type (both of which are elements of the Aterian industry of northwest Africa and Kharga oasis); and some microliths including a few microburins. The typological similarity between the proper Solutrean laurel-leaf point and the 'Sbaikian point, in the Parpalló material, made a strong case for the idea of an original Solutrean homeland in Africa. It might also be found that the Aterian type of tanged point was ancestral to the points of Font Robert in France, while the early appearance of the microliths precluded too late a dating for the Capsian and the microliths of claimed Magdalenian context in Europe.

The knowledge of a southward extension of the Magdalenian to the Parpalló area of Spain was also new. More exciting was the yield of engraved or painted slabs, in which at least some of the drawings were of recognizable animals. This artistic activity was evidenced from all of the levels; the painted drawings actually declined in proportion in the Magdalenian. The art, however, did approximate that of the Franco-Cantabrian style, and yielded none of the characteristic cinematic drawings of the proper East Spanish or group II art. The dating of this latter style had always been troublesome; the new Parpalló evidence would seem to force the date of group II to some time later than the latest layer in the Parpalló sequence, Magdalenian IV (but see below).

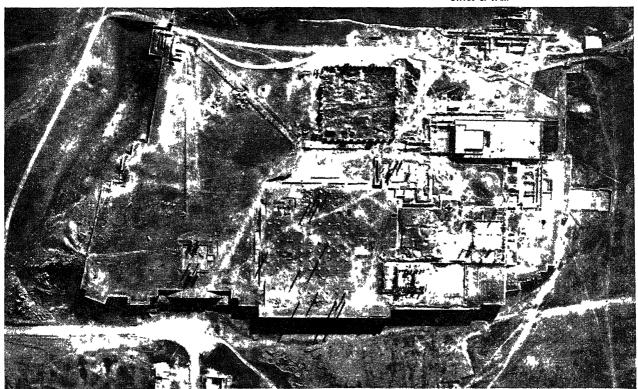

The really great discovery of the period in the field of prehistoric art, that of the Grotte de Lascaux, Dordogne, France, had not yet been published in full at the end of the decade, although various preliminary accounts and illustrations had appeared (e.g., Nature, 1941; Amer. Jour. of Archaeol., 1942; Proceedings, Prehistoric Society, 1945). The Lascaux cave comprises a large oval hall with axial passage, off which a lateral passage leads to a high gal-

lery. Numerous pictures of animals occur on the walls and ceilings, painted in bistre, red or black, upon a light background. Horses of at least three varieties, oxen, red deer, fallow deer and possibly Megaceros appear, but neither reindeer nor mammoth. Four bulls (Bos primigenius) are more than 5.5 metres in length. Some of the animals are shown pierced by arrows. One apparent scene shows a half-schematic drawing of a man lying on his back, while a woolly rhinoceros moves away. To the right of the figure of the man appears a bison, pierced by a lance, and with a large gaping belly wound from which entrails seem to escape. Under the feet of the man lies a hooked object, possibly a spear thrower, while in front of the figure stands a curious object, apparently a bird mounted on a stick.

The Lascaux paintings are assigned to the Périgordian industry (Chatelperronian-Gravettian). On stylistic grounds—especially as to the representation of horns and hoofs in twisted perspective, and in the attempts at composition—the Lascaux art is compared with the East Spanish art rather than with the Franco-Cantabrian style of the Magdalenian. But in a wider sense, it could be suggested that the Lascaux art may be ancestral to both these later styles.

In 1937, A. Rust published his Die Altsteinzeitlicher Renntierjägerlager Meiendorf, concerned with the first evidences of man on the frozen plains of northern Europe, as evidenced by his excavations at Meiendorf and Stellmoor, near Hamburg, in Germany. While the plain was still open tundra, reindeer hunters used to camp on it, between June and September, beside small meres. On the camping places only flint-blade tools survive, but the peat and mud of the adjacent meres have preserved tools in all stages of manufacture out of reindeer antler, antler

Ancient palace terrace of the Persian kings at Persepolis photographed from the air by the Oriental Institute of Chicago during its expedition of 1935–37 and published in *Flights* over Ancient Cities of Iran

harpoons, arrowheads, and knife handles with flint blades still in place and the skeletons of whole reindeer that had been cast into the waters, weighted with stones, as sacrifices. These reindeer were more closely allied to the American and east Asiatic species (Rangifer arcticus) than to the modern European reindeer (R. tarandus). Their hunters were but temporary visitants to these farnorthern tundras, having their winter quarters probably in southern Germany. Another encampment at Stellmoor, however, dates from a very much later time, when pinewoods had already invaded the tundra, although reindeer were still the chief game in north Germany.

H. L. Movius' The Irish Stone Age appeared in 1942, reporting on the excavation of six Stone Age sites-one in County Waterford and five in Northern Ireland. The first part of the book is an intensive re-examination of the late glacial and postglacial chronology of northern and northwestern Europe, with emphasis on Great Britain and Ireland. The geochronological setting is necessary, since the available Stone Age range of Irish material does not immediately conform to the classic industries of western Europe. The assemblages in question are called Early and Late Larnian (from a concentration of the finds along the coast at Larne). The earlier material is fixed in time by overlying beds of Late Boreal-Early Atlantic peat (at least c. 6000 B.C.); the Late Larnian assemblage was still being produced when the Neolithic peoples began to appear about 2000 B.C. The Early Larnian flint tools include blades, scrapers and picks; superficially tanged points, choppers and a few axes are added in the late assemblage. The producers of the Larnian materials seem to have been hunters, food collectors and fishermen, whom Movius believes to have reached Ireland from northwestern Europe before the Litorina submergence. They seem to have been descendants of the final Upper Palaeolithic peoples of northwestern Europe, and, although later arrivals in Ireland pushed them into the interior, their basic stock is present in the modern Irish people.

The status of prehistoric studies in North Africa was summarized by L. Braidwood's "The 'Palaeolithic' and 'Mesolithic' of North Africa and the Eastern Mediterranean" (Human Origins . . ., Selected Readings, Series II, The Univ. of Chgo., 1945-46). For the earlier ranges of time, R. Neuville and A. Ruhlmann's investigations of the quarry sites at Sidi Abderrahman, Casablanca, Morocco (La Place du Paléolithique Ancien dans le Quaternaire Marocain, 1941), were of importance. The stone tools from the earliest deposit (90-100 metre terrace, equated with the Günz glaciation of Europe by the excavators) are large and crude implements of quartzite and sandstone. It is of special interest that the label given these tools (certainly with the Abbé Breuil's approval) was "Clacto-Abbevillian." This implied a combination of the core (biface) and of the flake preparation traditions in this area, in earliest times. Other tool types were mentioned in the succeeding terraces of the area; Tayacian, Abbevillian, Acheulean, Levalloisian, and Mousterian were said to be accounted for.

Valuable atypical Upper Palaeolithic and Neolithic materials were excavated at Mugharet el-'Alyia (high cave) in Tangier by C. C. Coon for Harvard university. The important work of R. Vaufrey on the Capsian industry and its derivatives continued with the appearance of his L'Art Rupestre Nord-Africain (1939). This volume was the result of Vaufrey's examination of evidence for dating the rock art of French North Africa. He was convinced

that none of this art was earlier than the Neolithic of Capsian tradition, and that some of it persisted into historic times. The report was also a useful source on the general prehistoric archaeology of the area.

The general understanding of prehistory in Africa south of the tenth degree north parallel (i.e., nether Africa) increased considerably during the decade. In 1937, C. van Riet Lowe's "The Geology and Archaeology of the Vaal River Basin" appeared, in which the south African handaxe implements were fixed within the geological framework of the area. Later Prof. van Riet Lowe and his colleagues made a number of important contributions, including van Riet Lowe's "The Evolution of the Levallois Technique in South Africa" (Man, 1945), in which the role of the Levallois (flake facies) tool preparation tradition was examined in detail. The following quotation from this paper is an important statement of position:

It is extremely interesting to compare the European position with the South African. No element of the basic technical processes of the European Levallois is absent from South Africa. Every type of European Levallois core and flake has its South African counterpart-with this great and important difference: in South Africa the Levallois, in its inception, is an integral part of the Great Hand Axe Culture and it continues to remain so and to develop integrally with bifaced tools from an early stage of the Lower Palaeolithic right up to the end of the Mid-Palaeolithic or Middle Stone Age; i.e., first with the cultures that include comparatively heavy bifaced tools such as hand-axes, and later with those that include the lighter and more slender bifaced lanceolate or Solutrean-type points. In other words, the Levallois is not a separate culture in South Africa, but rather a process or technique which is inseparable from every material culture known to include post-Abbevilliantype bifaced tools-tools that resemble forms from Chelles, St. Acheul, Combe Capelle, La Micoque, and finally Solutré, i.e., the South African Levallois elements represent the wasteproducts of a series of developing cultures which aimed, inter alia, at the production of bifaced tools from Acheul-type hand axes in the beginning to Solutré-type lanceolate points at the

H. S. B. Cooke's "A Preliminary Survey of the Quaternary Period in South Africa" (Bureau of Archaeol., Archaeol. Series, Dept. of Interior, Union of S. Af., 1941) was a somewhat more general statement of the whole range of prehistory, and of geological and archaeological interrelationships.

For East Africa, T. P. O'Brien's The Prehistory of the Uganda Protectorate appeared in 1939. It was understood that van Riet Lowe and E. J. Wayland also had jointly prepared an extensive report on the geology and archaeology of the area, and that their conclusions differed from those of O'Brien in several fundamental respects.

While an anonymous note in Antiquity (1944) indicated that west Africa may have supported a long sequence similar to that of south Africa, the area was little known archaeologically. In 1939, R. Delcroix and R. Vaufrey (L'Anthropologie) demonstrated that elements of the Tumbian of Portuguese and French Guinea were derived from the Neolithic of Capsian tradition.

For the near east, 1937 marked the date of appearance of D. A. E. Garrod and D. M. A. Bate's *The Stone Age of Mount Carmel*, vol. 1, not only a great contribution to knowledge, but also a book which would undoubtedly remain, for years, a model excavation report. The main lines of the Mount Carmel sequence had already been blocked out in earlier preliminary reports—the sequence proceeding from materials of Tayacian type through Acheuleanlike and Levalloiso-Mousterianlike industries into a more localized succession of blade-tool industries

with Chatelperronian and Middle Aurignacian tools. Then, after an Atlitian (or debased Chatelperronian) came a gap, followed by the rich microlithic assemblage called the Natufian. The Acheuleanlike levels also yielded an increment of blade tools, by typological assessment, the earliest appearance of this type of implement. The Levalloiso-Mousterianlike levels yielded also the human fossils of *H. palestinensis*. The Mount Carmel sequence not only furnished Palestine with a known prehistoric past, but also demonstrated that this past differed from the classic European Chellean to Magdalenian sequence, especially at its later end.

Preliminary accounts of excavations in the cave of Kasr 'Akil near Beirut, Lebanon, by J. W. Murphy (Boston College Grad. School, Anthrop. Series, 1939) complemented the Mt. Carmel materials, and indicated that the Atlitian may have been followed by a variation of the Gravettian, with microliths.

Information on eastern Europe and Russia was not so readily available, but P. P. Efimenko's Paleolit i Neolit SSSR (1945) was an important key to knowledge of the area. This was a collection of about 21 papers by Russian archaeologists, reporting work done up to the time of the soviet union's entry into World War II. The papers mainly concern upper palaeolithic to neolithic materials, and have concise but usable French summaries. The volume also includes a very valuable list of palaeolithic sites in the U.S.S.R., complete up to 1938, and with brief notes and the principal bibliography on each site. The list is given in terms of primitive Mousterian and Clactonian, Mousterian, and Upper Palaeolithic and Epipalaeolithic, and the sites with materials so classified are then listed regionally for both European and Asiatic Russia.

There was also, for Russia, V. Gordon Childe's useful summaries in Man (1942-43), which included some details of the important Crimean cave site, Kiik-koba. The lower levels of this cave contain a Tayacian similar to that of Mt. Carmel; the upper levels yield an industry with some Micoquianlike hand axes, plus a larger proportion of flake points and side scrapers. Important occurrences of blade-tool industries are also accounted for, but Childe insisted that true Solutrean and Magdalenian materials could not yet be demonstrated from Russia.

Investigations of the Ice Age antiquity of the far east were carried on with relative intensity until the outbreak of World War II. Important detailed reports and several general summaries of the Choukoutien excavations, near Peking, China, were issued by W. C. Pei. H. De Terra and T. T. Paterson made significant discoveries in northwestern India, and De Terra and H. L. Movius worked together on the Pleistocene geology and archaeology of Burma. The result of all this work was summarized in some detail in Movius' admirable Early Man and Pleistocene Stratigraphy in Southern and Eastern Asia (see above). In this volume, the Pleistocene artifacts of China, Burma, India and Java are treated in terms of a chopperchopping tool tradition, which Movius believed to be unconnected with the tool preparation traditions of Europe. With his own Burmese materials as a control, Movius applied his scheme to the extant antiquities from the other areas, and arrived at a much more comprehensible classification than had previously been offered. The Burmese stone tools (called Anyathian by Movius) are of three major types: (1) the chopper, a large, crude scraper; (2) the chopping tool, usually a large pebble with flakes removed so as to give a sinuous cutting edge; and (3) the hand adze, produced from a roughly tabular piece of material, and provided with a single-bevelled adze bit. Movius' examination of the materials from the surrounding areas convinced him that they also fit, in a general way, into this chopper-chopping tradition. In northwest India, however, there was some evidence that a blending of eastern and western traditions presently took place.

Peninsular India, in fact, was shown by the materials collected by E. C. Worman, for Harvard university, to have supported an apparently flourishing prehistoric population which used tools of the western Acheul and Levallois facies. However, P. E. P. Deraniyagala (Spolia Zeylanica, 1945) was of the opinion that some of the early artifacts in Ceylon conform to the eastern chopper-chopping tradition.

It has already been suggested that the implications of Movius' interpretation were profound. Previously, any attempt to seek new world origins in old world archaeological materials had seemed sterile, as the artifacts in America are not generally comparable with those of Late Pleistocene Europe. There was another source to be examined; some of its materials had in fact already existed. but were relatively buried in that they had been cast into the European classificatory system, and thus it seemed impertinent to examine them.

Much more information was necessary before the true role of the far eastern chopper-chopping tool tradition became clear, however. As to its contribution to questions of new world origins, most of the finds made through 1946 seemed much too early to be pertinent to the new world. Also, knowledge of northeastern and arctic Asia was very limited. A useful summary of the archaeology of this area was E. M. Davis' "The Archaeology of Northeastern Asia" (Papers of the Explorers' Club, 1940).

Late Prehistoric Period: 8000-3000 B.C. and Later.— Several significant general studies appeared concerning the period when the first basic revolution in human economy (i.e., food production; domestication of plants and animals, settled village life) took place. Some of V. Gordon Childe's work has already been mentioned; his important Dawn of European Civilization appeared in its second edition in 1939, and a third edition was in press in 1946. C. F. C. Hawkes' Prehistoric Foundations of Europe (1940) was also useful for the same period; both books were concerned with the neolithic and bronze age developments of Europe and the circum-Mediterranean basin. Later general surveys of the near eastern village cultures and what led up to them, were in brief papers by R. and L. Braidwood (Human Origins . . ., Selected Readings, Series II, The Univ. of Chgo., 1946). Childe's "The Orient and Europe" (Amer. Jour. of Archaeol., 1939) stressed particularly the importance of near eastern stimuli on the development of food-producing societies in Europe, and also the difficulties still involved in dating the European materials.

The role of Iran in the earliest village culture stage became much clearer with the appearance in 1937-39 of both R. Ghirshman's two volumes, Fouilles de Sialk, près de Kashan, and E. F. Schmidt's Excavations at Tepe Hissar, Damghan. The site of Sialk yielded one of the very earliest examples of village-culture material yet known, while that of Hissar added very significant details to knowledge of the succeeding developments. For developments in the distinct southern and western areas of Iran, A. Langsdorff and D. E. McCown's publication of Tall-i-Bakun A was the most important contribution.

Two brilliant syntheses of these early materials were D. E. McCown's The Comparative Stratigraphy of Early

Iran (1942) and "The Material Culture of Early Iran" (Jour. of Near Eastern Studies, 1942), in which the two distinct developments in the north and east, and in the south and west, were traced through their courses and into the period when the incoming gray-ware cultures seemed to bring an end to both earlier traditions. McCown integrated his materials with those of early Mesopotamia, and made use of the collections deriving from A. Stein's reconnaissance in Persian Baluchistan.

Relatively little material appeared in the Baluchistan-Indus area proper which is antecedent to the Harrappan civilization (see below). S. Piggott's summary of the archaeology of the area (in Ancient India, 1946) was very useful, and McCown also contributed a useful preface on the role of this area in E. J. Ross's report (Jour. of Near Eastern Studies, 1946) on the pottery from Rana Ghundai, northern Baluchistan.

West of Iran, in Iraq, there was work of extreme importance carried on by S. Lloyd and F. Safar for the Directorate of Antiquities of the Iraq government. At Tell Hassuna (Jour. of Near Eastern Studies, 1945), south of Mosul in northern Mesopotamia, Lloyd and Safar recovered a remarkable sequence of materials in the range of the earliest village culture assemblages of western Asia. The basal layer in the sequence contained three superimposed camp sites with hearths, coarse pottery, and both chipped and ground stone tools.

Above the camp sites were at least six successive architectural phases, characterized by Lloyd and Safar as the Hassuna levels. The several-roomed adobe buildings of these levels contained three major groups of pottery, the Hassuna archaic, the Hassuna standard and the Samarran (the first group restricted to the lowest floors, the last group to the middle and upper floors). The first two ceramic groups were tentatively known from the minute exposure of Nineveh I-hitherto the earliest north Mesopotamian village material. Various small objects in clay, stone and bone appeared; the sustenance pattern was indicated by sickle blades, silos and the bones of domesticated sheep (or goats) and cattle as well as of wild animals. There were burials, but the bones seem to have been badly preserved, and no studies of the human physical types were yet available.

The Hassuna levels were superimposed by levels containing pottery of the Halaf range, then of the Ubaid range, and in the disturbed surface layer there was Assyrian pottery.

The importance of the Hassuna discovery was in the area of the exposure made and in the bulk of material reclaimed and presented from so early a range of village materials. The excavators possibly exaggerated the difference between the basal camp-site material and that from ' the Hassuna levels; since the latter was already present in Nineveh I, the claims made in press releases on Hassuna as to its being the earliest village yet known needed qualification (cf. Time, Nov. 12, 1945). Actually, insofar as means of dating were reliable for those times, there were excavated village materials of equivalent antiquity from Iran to Egypt. However, Hassuna's importance appeared to be self-evident; it also depended to some extent on the fact that the position of the Samarran pottery was stratigraphically fixed. Primarily, Hassuna contributed significantly to an understanding of the beginnings of settled life in the area where, subsequently, civilization made its first appearance.

Very important materials from subsequent village-cul-

ture levels in the same area were indicated by E. A. Speiser's preliminary reports on Tepe Gawra (Bull., Amer. Schools of Oriental Research, 1937–38; Asia, 1938). At this site, considerable exposures in the Halaf, Ubaid and following levels had been made, and the appearance of niche-decorated temples in the Ubaid period was most significant.

In Lloyd and Safar's work at Tell 'Uqair (Jour. of Near Eastern Studies, 1943), about 50 miles south of Baghdad, a temple of the Uruk period (the second of the three predynastic sequences in south Mesopotamia; i.e., the Ubaid, Uruk and Jemdet Nasr periods) was exposed in some area, and smaller soundings yielded material of all three of the predynastic sequences as well as some materials referring to historic times. The indicated stratification was, in brief, as follows: (1) the earliest or Ubaid material, from a small sounding which reached virgin soil after proceeding through seven layers of occupation; (2) the earliest traces of a platform prepared for a temple, but for which only architectural evidence was available; (3) the Uruk period temple, on its platform, and with interior walls decorated with frescoes; (4 and 5) two successive fillings of the platform, from which potsherds of the nonpainted but burnished Uruk variety appeared, as they had in the painted temple; (6) a layer with no surviving buildings but with painted pottery of the Jemdet Nasr type; (7 and 8) two successive occupations of a chapel, first with Jemdet Nasr painted ware and scarlet ware and with a new type of brickwork; and (9) traces of later Akkadian and Babylonian occupations on a small scale and without massive architecture.

The earliest, Ubaid assemblage was important in that a considerable variety of the characteristic painted pottery was recovered (actually more common in buff ware than in the supposedly most characteristic greenish ware) with painted motifs including representational drawings of birds and animals as well as the usual geometric repertoire. The Ubaid assemblage also included a considerable number of baked clay tools: sickles, long "nails" with hooked points, and some very remarkable shaft-hole axes of which one type definitely recalled the battle axe of Troy II type. Bone tools in bitumen hafts also appeared, as well as flint hoes and fragmentary clay figurines of the Ur Ubaid type.

The work of the Germans at Warka was continued up to the beginning of World War II, and P. Delougaz and

An important archaeological discovery of 1940 was the tomb of Pharach Psou Sennes, discovered by Prof. Pierre Montet of France on the site of ancient Tanis, Egypt. Montet is shown examining the silver sarcophagus after its lid had been removed

S. Lloyd's Pre-Sargonid Temples in the Diyala Region was concerned in part with some late prehistoric material, and included an ingenious suggestion for assessing dates of buildings by a count of the presumably annual layers of plastering on wall faces.

An important summary of knowledge of predynastic Mesopotamia was prepared by A. L. Perkins.

A considerable amount of important work took place in Syria, both in its upper Mesopotamian portion and to the west of the Euphrates. M. E. L. Mallowan's final report on Tell Chagar Bazar appeared (Iraq, 1937), and the same excavator then exposed a most useful sequence of materials at Tell Brak (Illustrated London News, 1938–39), with monumental architecture comparable with that of earliest historic times in southern Mesopotamia.

The first volume of the final Tell Halaf (H. Schmidt, 1943) publication reached the U.S.; the famous pottery from this site which gave its name to one of the early west Asian village cultures, seemed well presented. It was clear, however, that the site of Tell Halaf contains transitional Halaf-Ubaid and Ubaid pottery as well as the classic Halaf style.

Another important upper Mesopotamian site, Baghouz, with spectacular Samarran painted pottery, was described (Journal of Near Eastern Studies, 1944).

The final publication of the Oriental institute's excavations on the village-culture materials in the plain of Antioch neared completion in 1946; in it, knowledge of the earliest village materials of Syro-Cilicia was made clear. C. F. A. Schaeffer's Ugaritica, I (1939), included some details of the earlier levels of the remarkable coastal site of Ras Shamra; knowledge of the coastal sequence was elaborated by A. M. N. Ehrich's publication (Memoirs, Amer. Philosophical society, 1939) of the early Qal'at er-Rus materials, and by R. and L. Braidwood's soundings (Syria, 1940) near Tartous. Inland, at Hama on the Orontes, H. Ingholt's (Amer. Jour. of Archaeol., 1942) deepest levels also exposed early Syrian village materials. Essentially, the earliest Syrian village material is characterized by a dark-faced burnished pottery and a distinctive chipped and polished stone industry. Levels with this material presently show signs of slight Halaf influence, followed in turn by traces of a transitional Halaf-Ubaid ceramic style, and then by an intrusion of the north Iraq Ubaid pottery style in some quantity. The first marked appearance of metal tools comes in the succeeding period, linked on ceramic grounds to the Uruk of north Iraq type, and then follows a period of considerable importance for the comparative archaeology of earliest historic Egypt and Mesopotamia.

For southern Syria, which seems to have conformed more closely to the Palestinian province, the appearance of M. Dunand's Fouilles de Byblos, I (1939) containing the énéolithique cemetery material, was significant.

The basic outline of the early village sequence in Palestine was described in 1937 with the appearance of G. E. Wright's The Pottery of Palestine. Although subsequently excavated materials pointed to the necessity for minor revisions and additions to Wright's interpretation, the main lines were then drawn.

For the whole near east, it was only in Palestine that the gap in knowledge separating the extant food-gathering stage and early village-culture materials was said to be closed. The actual evidence on this point, supposedly connecting the rich cave-dwelling Natufian assemblage with the village material at the base of the mound at Jericho, was, however, far from clear. The question was somewhat complicated by the excavations of M. Stekelis at the

cave of Abū Uṣbas, where an Upper Natufian with pottery was reported (Bull., Amer. Schools of Oriental Research, 1942–43). The potsherds were enigmatic, but the whole assemblage (when fully described) might be found to refer to a coastal culture somewhat different from those indicated by the materials of early inland Jericho.

P. L. O. Guy and R. M. Engberg's Megiddo Tombs (1938), and G. M. Shipton's Notes on the Megiddo Pottery (1939) added to the growing list of publications on that site. N. Glueck's The River Jordan was a most successful popular account of the river's geography, archaeology and history, and followed Glueck's detailed studies of materials collected in extensive archaeological surveys in Trans-Jordan. Taken with other explored or excavated sites, Glueck believed his surveys made it possible to demonstrate that Chalcolithic civilization in the Jordan valley was widespread and based on an agriculture dependent on well-developed irrigation, a postulate which was interesting in view of W. C. Lowdermilk's suggested "TVA on the Jordan."

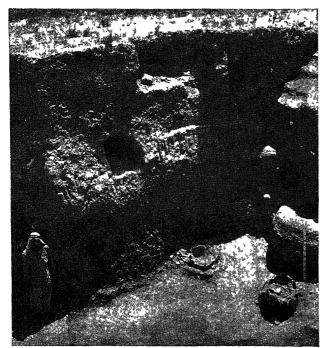

The second report on the large-scale early village exposure at Ghassul appeared, and the Jewish Palestine Exploration society began explorations at Khirbet el-Kerak, near Galilee.

For Egypt, perhaps the most valuable work for late prehistoric times was the appearance of G. Brunton's Mostagedda and the Tasian Culture (1937), in which the sequences of predynastic and early dynastic cultures were set forth with discernment in a summary of knowledge to that date. Several important papers by A. Scharff appeared, of which "Die Frühkulturen Ägyptens und Mesopotamiens" (Der Alte Orient, 1941) was concerned with the evidence of early interrelationships between Egypt and Mesopotamia. H. Frankfort's "The Origin of Monumental Architecture in Egypt" (Amer. Jour. of Semetic Languages, 1941) was a penetrating examination of the same subject matter; so, also, was H. Kantor's "The Early Relations of Egypt with Asia" (Jour. of Near Eastern Studies, 1942). Kantor also examined the evidence for a separate late period in her "The Final Phase of Predynastic Culture" (ibid., 1944), and concluded that the Semainean had little substance in its own right.

There was little actual excavation in predynastic horizons in Egypt during the decade 1937-46, save for the continuance of the Austrians at Merimde village up to the beginning of World War II.

In Anatolia, some foreign excavations were in progress up to 1940, and the Turkish Historical society was commendably active. H. Z. Koşay continued his important work at Alaca Höyük (1944), from which more of the spectacular copper age tombs were ably reported, and also materials from the preceding chalcolithic levels. The Belleten noted important new material from the sites of Dündartepe and Tekeköy, near the Black sea port of Samsun, presented by K. Kökten and N. and T. Özgüç; this included dark-faced burnished pottery, mother-goddess figurines, and metals from the little known area of northern Anatolia. A summary of the status of Turkish protohistoric chronology by T. Özgüç, also appeared, as well as Ş. A. Kansu's notes on the mesolithic of Turkey.

H. H. von der Osten's three-volume report on the Alishar Hüyük appeared in 1937, giving details of the key sequence established at that site in central Anatolia by the Oriental institute. W. Lamb's report on Kusura appeared in the same year. H. Goldman's excavations at Tarsus, in Cilicia, reached late prehistoric levels (Amer. Jour. of

Lowest of six building layers excavated at Tell Hassuna in the upper Tigris valley, Iraq, as reported in 1945. Remains at this level were said to form the earliest trace of settled community life yet unearthed

Archaeol., 1937-40), and thus filled one of the gaps in the Mersin sequence. At this latter site, J. Garstang (Liverpool Ann. of Arch. and Anthrop., 1937-39, 1940; Amer. Jour. of Archaeol., 1943) exposed extremely important village material, especially valuable in elaborating knowledge of the earliest Syro-Cilician village cultures. Then, following a gap at Mersin of somewhat undetermined length, came a sequence demonstrating how the later village materials of Cilicia conformed more to those of the Anatolian than of the Syrian province.

For western Anatolia, C. Blegen's preliminary reports on the test excavations at Troy continued (Amer. Jour. of Archaeol., 1937-39) until the campaign was finished. Blegen's careful checking of the Troy sequence was of tremendous importance, as the materials from the site were crucial in questions of west Asiatic and European connections.

The great activity concerning early village remains in Cyprus had somewhat slackened by 1937, but P. Dikaios reported (*Illustrated London News*, 1939) the discovery of an early nonpottery neolithic site at Khirokitia.

A significant summary of the village-culture prehistory of the Aegean area by S. S. Weinberg appeared in 1946 (Amer. Jour. of Archaeol.). Weinberg's note on prehistoric Corinth (Hesperia, 1937) examined the early ceramic interrelationships of mainland Greece and the areas beyond. J. D. S. Pendlebury's The Archaeology of Crete (1939) was a landmark, in which all prehistoric (as well as historic) Cretan materials and their interconnections were treated with discernment. The most important bulk of lately excavated materials in the Aegean referred to the northern Greek (Macedonian) area, for which there were the various Olynthus reports and W. A. Heurtley's Prehistoric Macedonia (1939). These materials, comparable on the one hand with some of the Thessalian village materials, were of extreme importance in linking the near east to Danubian Europe.

The summaries of Childe and Hawkes on the Neolithic

and Bronze Ages of Europe have already been noted above. Archaeological excavations in that unfortunate continent were understandably curtailed during most of the decade 1937-46. Some very important results were obtained in Scandinavia through the works of T. Mathiassen, J. Troels-Smith and others (Proceedings, Prehistoric society, 1945). It became clear that there were three or four transgressions in the sub-boreal climatic phase; that the Ertebolle assemblage, with pottery, lasted all through the Atlantic phase and coexisted with the Dolmen period at the end, and that Dolmens are Sub-Boreal. The excavation of two contemporary and neighbouring sites, one Ertebolle and the other neolithic, yielded such dissimilar materials that it became clear the latter was not derived from the former, and an immigration of new peoples had to be postulated. Important studies of the later prehistory of Denmark, by both H. C. Broholm and J. Bronsted, appeared.

In Britain, a beaker (type of vase distinctive of the very beginning of the Bronze Age) was found at Rinyo, in the Orkney islands, and made possible the dating (c. 2000-1500 B.C.) of the already famous village at Skara Brae. Both sites yielded roomy huts with elaborate built-in furniture all of stone, showing the amenities of the early foodproducing stage even in peripheral regions. H. Godwin (Nature, 1944) produced evidence from pollen analysis to show how neolithic man cleared considerable land areas of forest by burning. While few full scale excavations were carried on in Britain during World War II, several important syntheses appeared. V. Gordon Childe's Prehistoric Communities of the British Isles (1940) was scheduled for its second edition, while J. G. D. Clark's Prehistoric England (1945) and J. and C. Hawkes Prehistoric Britain (1943) were excellent popular accounts. British archaeologists gave considerable thought to the future, and important statements of problems in general European archaeology appeared in Occasional Paper, No. 6, of the London Institute of Archaeology.

A handsome publication of the more rational German approach to late prehistory was W. Buttler's Der Donauländische und der Westische Kulturkreis der Jüngeren Steinzeit (1938). In it, the author's remarkable excavations at the Köln-Lindenthal neolithic village were drawn into the much broader framework of European archaeology.

Perhaps the most useful information on later Russian activities appeared in V. Gordon Childe's summaries (Man, 1942-44), and by V. Avdiyev (Amer. Jour. of Archaeol., 1945) and H. Field (Amer. Anthropologist, 1946). The south Russian-Caucasus area saw considerable activity until the German attack on the U.S.S.R. As unalloyed copper appears to have been used until the Iron Age began, the old style Bronze-age classification was of little use in the area. The successive assemblages characterized by the use of copper were divided into four periods; in each period, there are details with important comparative bearing, both toward the near east and toward Europe.

In the more northerly forest zone, a sort of neolithic with pottery preceded the beginning of food production (best evidenced by the Fatyanovo grave material). At Olem Ostrovo, a remarkable neolithic cemetery with upright burials was found. In the Fatyanovo, burials were contracted, or sometimes cremated, and placed in pits; meat bones of domestic animals and some artifacts were used as grave goods. The Russian prehistorians believed this new assemblage represented an adaptation of the older fisher-hunter economy, with livestock and some industrial habits having been borrowed from the south Russian area.

A collection of short reports on the late prehistoric archaeology of the Ural-Kama area was Archeologicheskie Pamiatniki Urala i Prikamia (P. N. Tretiakov, ed., 1940), well illustrated, and with French summaries. James Gaul's (Papers, Peabody Museum of Amer. Archaeol. and Ethnol., Harvard Univ., 1943) article on the Siberian Bronze Age in the Yenisei valley was an important contribution on relatively unavailable material from a remote area. Food production (or at least pastoralism) appeared to go back to at least 2000–1500 B.C.

Although little excavation took place after 1937, knowledge of the later prehistory of the far east became more readily available with the appearance of J. G. Andersson's "Researches into the Prehistory of the Chinese" (Bull., Museum of Far Eastern Antiquities, 1943), and of R. Heine-Geldern's Prehistoric Research in the Netherlands Indies (1945). Andersson's volume underlined the fact that late Chinese prehistory was still very much in the survey stage, with great preoccupation toward painted pottery, and with few adequately exposed village assemblages. He seemed strongly convinced that superficial resemblances between the painted pottery styles of China and of the west were not sufficient to demonstrate connections or western stimulation. Andersson anticipated that typologically earlier material than that in hand would yet be discovered, and made the point that it was not until the end of the Neolithic that village materials suddenly made their first appearance.

Heine-Geldern showed that while mesolithic and earlier remains were relatively available from caves in Indonesia, the open village sites of early food producers were found only by accident, and hence that early village materials were still relatively scarce. Large numbers of polished stone tools of the full Neolithic were available, but not chronology, based on stratigraphic sequences. The end of the Neolithic was also unclear. Heine-Geldern postulated a time soon after 600 B.C. for the appearance of the Dongson bronze celts, and that iron appeared not long afterward. The methodology used in this area depended considerably on ethnohistorical and linguistic evidence.

Early Historic Period.—Probably the most important step during the decade 1937-46 in increase of knowledge of ancient times was the information on thousands of cuneiform documents from the site of Mari, on the middle Euphrates, in Syria. Here, A. Parrot's French expedition found, in the palace of King Zimri-Lim of the 18th century B.C., the clay tablets containing a correspondence of such historical significance as to rival the Tell el Amarna letters. G. Dossin and F. Thureau-Dangin (e.g., Syria, 1938 ff.) were active in the publication of the Mari tablets. Through 1946, the most important implications of the contents of the Mari letters were in the direction of reducing the chronology of western Asia.

Before the actual sequence of events in the lowering of the chronology are detailed, it must be remarked that supporting evidence was derived from the continuation of significant excavations by L. Woolley at 'Atshanah-Alalakh in northwest Syria, by C. F. A. Schaeffer at Ras Shamra-Ugarit on the north Syrian coast, and by the publication of the Assyrian king list discovered by the Oriental Institute at Khorsabad (in 1932-33).

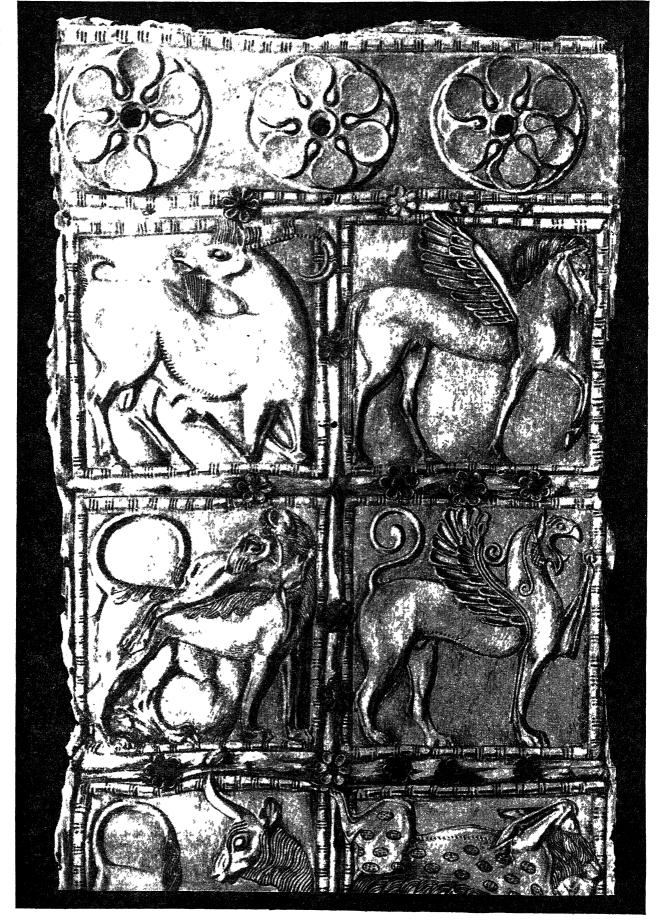

Up to 1939, the standard textbooks were placing the date of accession of the great Babylonian king and law giver, Hammurabi, at about 2000 B.C. One was assured that the Mesopotamian chronology was for all intents and purposes as reliable as that of Egypt, where a tolerance of little more than 25 years was needed to express the first date of the 12th dynasty (cf. W. F. Edgerton, Jour. of

Near Eastern Studies, 1942, who assessed the probable date of Amenemhet I as 1989 B.C.). T. Jacobsen's penetrating Sumerian King List (1939) gave Hammurabi's dates as 2067-25 B.C. At this point, the Mari correspondence began to appear, and W. F. Albright pioneered the use of this evidence, and lowered the accession date of Hammurabi to about 1870 B.C.; slightly later, Albright found comparative Egyptian and Syrian evidence to lower it again to about 1800 B.C. Late in 1940, S. Smith's brilliant Alalakh and Chronology appeared, in which more archaeological and historical evidence was balanced together to give dates of 1792-50 B.C. for Hammurabi. For all essential purposes, Albright agreed to these dates. Then came the belated publication of the Khorsabad king list, wherein A. Poebel (Jour. of Near Eastern Studies, 1942-43) assessed the dates of Hammurabi's contemporary, Samsi-Hadad I of Assyria, as 1726-1694 B.C. In consequence, Albright (Bulletin of the American Schools of Oriental Research, 1942) reduced his dates again by 64 years (one Venus cycle, a factor in the calculations), thus setting Hammurabi's dates at 1728-1686 B.C.

This lowest dating had not yet been universally accepted in 1946, and Smith (Amer. Jour. of Archaeol., 1945) brought evidence of the coexistence, in a Cretan tomb of the M.M. I period, of a Babylonian cylinder seal of Hammurabi age and two 13th dynasty Egyptian scarabs, to support his earlier dating. Albright also maintained his later dating (Bulletin of the American Schools of Oriental Research, 1945) by means of both comparative archaeological and philological evidence. But whether Hammurabi mounted the throne in 1792 B.C. or 1728 B.C., the marked general depression in his date (from the 21st century B.C.) was sufficient to call for a depression in the dating of all west Asian and Aegean materials which had been bound to the old Babylonian chronology. It was Professor Albright's opinion that dates given in the Aegean (when derived from Babylonia) had been three to four centuries too high, and that even the Cappadocian tablets had been dated as much as six centuries too high. It may also be noted that the geographical range of the evidence noted here demonstrates most pointedly how internationalized the eastern Mediterranean world of the 18th century B.C. had already become.

Even for the war years and those just preceding them, many useful and detail-filling discoveries were made or published in the historic range; of these only the highlights can be treated. For Iran, E. F. Schmidt's The Treasury of Persepolis (1939) was a step forward in the knowledge of Darius' capital, as were also the details of Shahpuhr's inscription (Amer. Jour. of Semetic Languages, 1940). Remarkable Parthian statues in bronze were recovered from Shami, and R. Ghirshman excavated a Sassanian palace with mosaics, and a fire temple at Shapur. The Metropolitan Museum of Arts excavations at Nishapur produced the first early Islamic paintings ever found in northeastern Iran. J. Hackin's work at Begram, in Afghanistan, produced important Graeco-Roman and Oriental contact material, from the capital of ancient Kapisi.

The Indus civilization and periods subsequent to it became better known through E. Mackay's further work at Mohenjo-Daro, and by his publication of Chanhu-Daro (1943) for the Boston museum. This latter site included important post-Harrappan (Indus civilization) materials of the Jhukar and Jhangar periods. V. Gordon Childe (Antiquity, 1939) and S. Piggott (Ancient India, 1946) made useful summaries of the archaeology of this area.

For historic Mesopotamia, the final publication of the key Diyala sites, excavated by the Oriental institute's Iraq expedition, had been well begun; five volumes had appeared by 1946, dealing mainly with architecture and sculpture. H. Frankfort's Cylinder Seals (1939) set down the broad stylistic lines and chronological sequence of the important western Asian glyptic art. T. Baqir made significant excavations in the Kassite levels of 'Aqar Quf-Dur Kurigalzu, gaining partial plans of three large temples and information on the founding of the ziggurat. R. F. S. Starr's Nuzi report appeared (1937-39), with details of the sequence in this more northerly site at which a large area and many antiquities and cuneiform letters of the mid-second millennium B.C. had been exposed. I. J. Gelb's penetrating Hurrians and Subarians (1944) offered proof that these elements actually formed two different ethnic and political entities. The active Iraq Directorate of Antiquities reclaimed important later materials at Der, Wasif, Hajjoj and Samarra, adding to knowledge of Neo-Babylonian, Graeco-Roman to Sassanian and Islamic times, and the University of Michigan, Ann Arbor, Mich., continued the exposure of Selucia-on-the-Tigris. In the field of philology, S. N. Kramer's study and interpretation of the long neglected texts from Nippur revolutionized knowledge of one of the oldest higher cultures in the

In inland (Mesopotamian) Syria, the brilliant results at Mari have already been noted. M. Mallowan concluded his campaign at Chagar Bazar, and commenced important excavations at Tell Brak, near Hassetché. As well as earlier village material, written evidence was found to indicate that the site must have been an important trading centre in the time of Narâmsin. On the Euphrates, the long and important campaign at the Graeco-Roman city of Dura-Europus by Yale university, New Haven, Conn. and the Louvre, Paris, came to a successful close, and most of the final reports appeared. The later campaigns at Ras Shamra yielded public buildings, fortifications and administrative documents of great importance; philological work on the new Semitic documents from the site were of great literary and mythological significance. M. Dunand's complete publication of the new syllabic script from Byblos (Jebeil) was also of great importance. For the Graeco-Roman period, explorations in the vicinity of Antioch were continued under the committee from Princeton university, Princeton, N.J., the Louvre museum, and several U.S. museums; the Service des Antiquités continued its work on architecture of the same period at Palmyra.

Palestinian archaeology benefited by the appearance of W. F. Albright's excellent synthesis, From the Stone Age to Christianity (1940), and by the more popular What Mean These Stones (1941) by Millar Burrows and The Ladder of Progress in Palestine (1943) by C. C. McCown. The more important reports of specific excavations concerned four temples at Beth Shan (Beisan) illustrating Egyptian contacts with Palestine, N. Glueck's work at the industrial and port site of Tell el-Kheleifeh on the Red sea Gulf of 'Aqaba, C. H. Kraeling's edition of the architecturally important Gerasa publication, and B. Maisler's work on the late materials of Sheikh Abreiq. Gordon Loud's The Megiddo Ivories (1939) presented finds of greatest importance for the history of Phoenician art.

In Egypt, the fundamental work of W. B. Emery for the Service of Antiquities at Saqqara yielded new information

Detail of the gold garment of one of the chryselephantine statues dating from the 6th century B.C., found by French archaeologists at Delphi, Greece, in 1939. Restoration by Gilliéron (after the Bulletin de Correspondance Hellénique)

on the architecture, small objects, and especially copper implements of the 1st and 2nd dynasties. Z. Y. Saad also cleared about 735 1st dynasty tombs at Helwan. Striking new scenes appeared on a causeway to the pyramid of the 5th dynasty Pharaoh Unis, which promised to enlarge knowledge of royal ceremony at this early period. M. Chevrier of the Service of Antiquities reassembled the delicate little 12th dynasty shrine at Karnak. The most spectacular discoveries were those of Pierre Montet at Tanis, where tombs of several of the pharaohs of the 21st and 22nd dynasties featured an ornate art and a considerable amount of costly material. E. Drioton and J. Vandier's L'Egypte (1938) was an excellent detailed history; for the general reader, the most pleasing statement of the field was in G. Steindorff and K. C. Seele's When Egypt Ruled the East (1942).

One of the more important concluding statements of the Swedish Cyprus expedition was Erik Sjoqvist's Problems of the Late Cypriote Bronze Age (1940). J. F. Daniel's careful excavations at Kourion, in Cyprus, yielded examples of the last direct descendant of the Minoan linear script.

In Anatolia, Turkey, work in historic horizons proceeded at Bogazköy, Malatya, and Tarsus until interrupted by World War II. Important clearances were continued by the Turkish Historical society, and it was reported that H. T. Bossert's work in the first millennium strata of Karatepe, in Cilicia, would be of extreme significance. His Alt-Anatolien (1942) was an excellent summary with profuse and fine illustrations. Great papers by I. J. Gelb, B. Hrozny and P. Meriggi appeared in the field of Hittite hieroglyphics, and H. Güterbock and K. Bittel published important cylinder seals from Bogazköy and Troy. Blegen's important work at Troy, already noted above, also concerned the historic period.

The find of the period in Greece was Blegen's discovery, at Pylos, of some 600 tablets in early (Greek?) script. The archaic terra cotta sculptures and bronzes of Olympia were unusual, and the first chryselephantine sculptures ever to be found appeared at Delphi. Two wonderful new kouroi (youth sculptures) were discovered, and G. Richter's book, Kouroi (1942), appeared. The U.S. clearance of the Athenian Agora proceeded up to the beginning of World War II, and an important Mycenean tomb, as well as a wealth of detail on the classical period, were accounted for in preliminary reports in Hesperia. Work was resumed at the Agora by H. Thompson. The detailed reports on Corinth also continued. An important book was J. D. Beazley's Attic Red-Figured Vase Painters (1942).

The most remarkable work on Roman Italy was the culmination of the huge official project at Ostia by 1941, and A. Maiuri's continuing work at Herculaneum and Pompeii. At Herculaneum a small Christian chapel was found in an upper story room.

Accidental finds outnumbered planned excavations in Europe. G. Bersu's minute examination of the settlement site at Little Woodbury cast fresh light on the economy and sociology of pre-Roman Britain. By far the most spectacular discovery in western Europe during 1939, and one of the most remarkable finds ever made in England, was the ship grave of an Anglo-Saxon king found in the Sutton Hoo tumulus beside the river Deben in Suffolk. Careful excavation directed by C. W. Phillips revealed not only clear traces of the boat but also the outline of the ship itself—a vessel 82 ft. long and 16 ft. in the beam. The centrally located burial contained jewellery and per-

sonal belongings of barbaric splendour. The most impressive feature of the Sutton Hoo treasure was a set of provincial Byzantine plate; one magnificent silver dish bears the marks of the reign of the Emperor Anastasius I. It was suggested that the chieftain may have been Redwald, king of the East Angles (died c. A.D. 620), who was the first of his lineage to become high king of England.

B. A. Kuftin's work in the Trialeti province west of Tiflis testified to the vigour of Russian archaeological interest. The sites examined in this area ranged from the Copper Age to Sassanian times; great interest was connected with the Trialeti materials contemporary with Mycenean Greece.

The publication of the newly uncovered and conserved mosaics of Santa Sofia in Constantinople (Istanbul) was reported to be in press in 1946. Remarkable Islamic remains were cleared by D. Schlumberger at Kasr el-Heir al-Gharbi in Syria, with frescoes and stucco sculpture. Another important example of Islamic art and architecture appeared in the Umayyad palace site of Khirbet al-Mefjir in Palestine, and the 10th century summer palace of the Cordova caliphs in Spain was exposed.

For China (where the war began in 1937), Dr. Chen Meng-chia kindly supplied the following summary:

During the war all excavations were halted and a report on the Academica Sinica's work at Anyang was prepared. In 1945 a monograph called Liu t'ung pi lu was published. Three important articles by Shih Chang-Ju, excavator of Anyang, were included in this monograph. The general report on Anyang was awaited as a significant event in Chinese archaeology.

In 1938-39 the National Central museum made an excavation in Tali in northern Yunan province, publishing two memoirs in one volume; Report on an Archaeological Survey of the Ts'ang-erh District, Yunan, with an English summary. Part one is the report on four sites with 38 prehistoric residences. The earliest stage of the prehistoric discoveries probably corresponds with the Neolithic; the date of these sites is contemporary with Han or late Chou, two or three centuries B.C. Part two is a report on inscribed tiles collected at the foot of the Tien-tsang mountains. The inscriptions are in both Chinese and non-Chinese languages. They were probably made in the Nanchao kingdom, c. A.D. 738-902. This was the only scientifically excavated material concerning this culture of southwest China.

During 1927-33 the Sino-Swedish expedition made various excavations in northwest China. They found a great many bamboo and wooden slips at the capital of Ningsia province. These were the written documents of the Han dynasty. In 1943 Lao Kan of the Academia Sinica published a translation, and in the following year his researches, both very important in the study of Han history.

In 1944, Tung Tso-pin of the Academia Sinica published his work on the chronology of the Yin dynasty based on oracle-bone material found at Anyang. In the same year Chen Meng-Chia published a book on the chronology of the Western Chou based on bronze inscriptions and the "Bamboo Annals" found in A.D. 281.

The National library of Peking, in 1941, prepared to publish a series of archaeological researches edited by Chen Meng-Chia. About ten works had been put in press by 1946, but with the single exception of Chen's Chinese Bronzes in Foreign Collections, none had been published.

In 1940 the Peking office of the Harvard-Yenching institute published Jung Keng's The Bronzes of Shang and Chou in two volumes with 1,000 plates. The first volume is an introduction to the study of Chinese bronzes. In 1945 Chen Meng-Chia was sponsored by Harvard-Yenching to work on a corpus of the Chinese Bronzes in American collections for a period of two years.

In 1937 a catalogue was published in the Honan Provincial Gazette, containing 100 bronzes of Early Eastern Chou found in Honan province in 1923. In 1938 a catalogue of Hsün-hsien was published. These were bronzes of western Chou excavated by the Academia Sinica in 1932.

In 1936-37, a great quantity of lacquer, pottery, wooden sculpture and bronzes was found in Changsha. They were of the later Eastern Chou and Han dynasties. In 1937 Shang Ch'eng-tso was sent by the Institute of Chinese Culture Studies of the University of Nanking to investigate these finds. In 1939 he published An Account of Archaeological Excavations in Ch'ang-sha.

Before 1937, the excavations under various institutions placed major emphasis on the pre-Han period. During the war many Han tombs were found in Szechwan province. Full reports on these spectacular materials had not yet been published in 1946. (R. J. B.)¹

Western Hemisphere

In contrast to archaeology in the eastern hemisphere, the decade 1937 to 1946 inclusive was the most eventful in the history of American archaeology. Throughout the western hemisphere there was a florescence of archaeological research. The acceleration of research programs was the greatest the new world had ever known.

The socio-historical background of this accelerated archaeological research in the western hemisphere included an economic depression and a terrible war. Out of the depression was born the federal financing of archaeological projects in the U.S. in order to provide legitimate employment for thousands of unemployed men and women. More than \$1,500,000 was spent annually on archaeological projects in the southeastern U.S. alone. Moreover, the production of scientific data thus financed did not compete with established businesses and industries.

This federally financed archaeology in the U.S. not only made possible excavation and research on a scale previously undreamed, but also salvaged materials and information from important sites in areas later inundated as a result of the dams built by the Tennessee Valley Authority.

The federal financing of archaeology not only made possible excavation and research under the directorship of institutions that otherwise could not have afforded such programs, but also made possible the salvaging of materials and information from archaeological sites in danger of destruction from industrial expansion or agricultural activities.

Archaeology undertaken on such a large scale naturally developed techniques and methods somewhat different from those used previously. The most outstanding innovation was the development of assembly-line techniques for use in the field, but especially in the laboratory. The processing of archaeological information and materials was similar to the production methods of the factory.

This system was excellent for the collecting, analyzing and synthesizing of raw data, but was too rapid for the careful preparation of interpretative reports. As a result, much of the archaeological work awaited reporting and

¹The writer is especially indebted to W. F. Albright, Chen Meng-Chia, V. Gordon Childe, F. C. Cole, I. J. Gelb, D. E. McCown, M. B Smith, Mrs. Dorothy Thompson, F. O. Waage, S. S. Weinberg, J. A Wilson and G. E. Wright for helpful suggestions.

World War II.

While federally financed archaeology was being undertaken, private and state institutions were not idle. Many

Collier, Alfred E. Hudson and Arlo Ford (1942).

universities and museums carried out excavations and researches of the utmost significance, but on a somewhat

smaller scale than that of the federal programs.

While the depression was indirectly responsible for the archaeological boom in the U.S., the approach of war was indirectly responsible for widespread archaeological activity in Latin America. While hostilities were still confined to the eastern hemisphere, the strengthening of cultural relations among the western nations became not only desirable, but necessary. An ideal factor in strengthening these relationships was the bond of scholarship and interest in a common field such as American archaeologyburied history shared by all the nations of the new world. Consequently, with the objective of contributing both to pan-Americanism and archaeology, the Institute of Andean Research, supported by the art committee of the Coordinator of Inter-American Affairs, sent 12 archaeological expeditions to Latin America in 1941-42. There were, of course, many other significant archaeological investigations made in Latin America during the decade. Work undertaken by various institutions either in Latin America or in the U.S. contributed materially to the prehistory of Latin America. However, the activities of the Institute of Andean Research were outstanding for comprehensiveness and co-ordination.

In addition to the federally financed archaeological projects in the U.S. and the work of the Institute of Andean Research in Latin America, there were many other programs of research in the hemisphere. Some of these programs were new, others were continuations of long-term projects. Such programs were undertaken by universities, research institutions, museums, bureaus, local governments and (in Latin America) national governments.

More than any previous decade, the period 1937–46 was characterized by an awareness of problems and attempts to solve problems rather than random excavation aimed merely at discovery. For the first time in the history of American archaeology, the broad outlines of prehistory began to emerge on a continental scale.

Early Man.—The contemporaneity of the Paleo-Indian with glacial phenomena and animals now extinct was well established during the decade. Some additional Folsom finds were made and some new Paleo-Indian cultures were described such as the Cochise culture (Edward B. Sayles and Ernst Antevs, 1941) and the Sandia culture (Frank C. Hibben, 1941). An excellent summary of Paleo-Indian archaeology by Frank H. H. Roberts, Jr. was published in 1940.

Arctic America.—Henry B. Collins (1937) demonstrated the sequence of Eskimo cultures: Old Bering Sea, Punuk, Birnirk and Thule in northern Alaska. The newly-discovered Ipiutak culture was described by F. G. Rainey (1941). Ales Hrdlicka's reports (1944–45) presented cultural details from southern Alaska. The Dorset culture of the eastern Arctic was elaborated and extended through the researches of Canadian, Danish and English archaeologists. The most significant innovation in Eskimo archaeology was the successful introduction of dating sites by dendrochronology (J. Louis Giddings, 1944). A summary of Eskimo prehistory by Collins appeared in 1940.

Northwestern and Western North America.—P. Drucker (1943) reported the results of his survey of coastal British Columbia and outlined the available data of northwest coast archaeology. The results of research in the Columbia

Collier, Alfred E. Hudson and Arlo Ford (1942).

The prehistory of Indian California was presented in reports by Franklin Fenenga, R. F. Heizer, J. B. Lillard, W. R. Wedel and others. J. H. Steward (1940) sum-

marized the archaeology of the vast and little-known Inter-

montane (Great Basin) area.

Southwestern North America.—During the decade there was a considerable increase in the knowledge of the history of the three principal culture patterns: Anasazi, Hohokam and Mogollon.

Hohokam culture and periods were best described by H. S. Gladwin, E. W. Haury, E. B. Sayles and Nora Gladwin (1937). Some important contributions to Anasazi culture history were made by Ralph Beals, G. W. Brainerd and Watson Smith (1945); H. S. Colton and L. L. Hargrave (1937); Haury (1945); P. S. Martin (1938–39). H. P. Mera (1939–40); E. H. Morris (1939) and others.

Mogollon culture and periods were elucidated by Haury (1940, 1943); Martin (1940, 1942); and P. H. Nesbitt (1938). Important contributions to the solution of the problem of Navajo archaeology were made by E. T. Hall (1944) and Dorothy L. Keur (1941).

A brief summary of southwestern archaeology by Frank H. Roberts, Jr. was published in 1937. An elaborate sum-

mary by John C. McGregor appeared in 1941.

Eastern North America.—In this area the decade witnessed the emergence of archaeological interpretation from a state bordering on chaos to a recognition of the broad outlines of the prehistory of the region. Although much of the basic information was unpublished it was, nevertheless, generally known to all specialists working in the area. Over most of the region the archaeological evidence suggested a development from cultures based upon hunting, fishing and food collecting to cultures based upon agriculture. Particularly in the Mississippi valley, burial mounds and, later, pyramidal temple mounds were associated with the agricultural culture stages. Pottery, tobacco pipes, copper tools, weapons and ornaments, the bow and arrow, stone and shell hoes, and other artifacts or customs appeared at various stages of this cultural development. Important papers on these subjects were published by Fay-Cooper Cole (1943); J. A. Ford and G. R. Willey (1941); J. B. Griffin (1943, 1946), J. D. Jennings (1941); W. A. Ritchie (1944); W. Duncan Strong (1940) and

The Caribbean Area.—The distribution and succession of Caribbean cultures, almost unknown prior to the decade 1937–46, were described by C. Osgood (1942), F. G. Rainey (1941) and Irving Rouse (1939, 1941, 1942).

Mexico and Central America.—In Mexico new cultures were discovered and previously known cultures were augmented by additional finds or analyses. Among the significant reports of research in this area were publications by Alfonso Caso (1938), Philip Drucker (1943), G. F. Ekholm (1944), Isabel Kelly (1945), M. W. Stirling (1943), G. C. Valliant (1941) and others.

In Yucatan and Central America important archaeological researches were undertaken by a number of organizations, especially the Carnegie institution of Washington, D.C. Additional information about the famous Maya civilization was obtained and some new cultures were discovered. In addition to the reports of the Carnegie institution, some of the significant contributions to the archaeology of this area were C. L. Hay et al (ed.) (1940), J. M. Longyear (1944), S. K. Lothrop (1937), Doris Stone

(1943) and J. E. S. Thompson (1943).

South America.—Tremendous strides in the archaeology of South America were made during the decade. Particularly outstanding for its work in this field was the Institute of Andean Research. Although there were many excellent reports of South American archaeology by scholars of many different nations, all of the knowledge was excellently summarized in the Handbook of South American Indians edited by Julian H. Steward and published as Bulletin 143 of the Bureau of American Ethnology, Washington, D.C. This handbook was outstanding and unique. With archaeological contributions by Wendell C. Bennett, Junius B. Bird, Donald Collier, John M. Cooper, Gregorio Hernandez de Alba, Alfred L. Kroeber, Rafael Larco Hoyle, Henri Lehmann, Samuel K. Lothrop, John Howland Rowe, Luis Valcarcel, Gordon R. Willey and others, all of the known prehistory of South America was made easily available for the first time. (See also ANTHROPOL-OGY.)

Archery

Archery as an organized sport had its beginnings in the United States in the first half of the 19th century, but it was not organized on a national scale until 1879, when the National Archery association of the United States was formed to promote and direct the sport and to hold an annual tournament to determine the archery championships of the United States.

Except for the war years of 1917-18 of World War I and the war years of 1942-45 of World War II, the National Archery association held a championship tournament each year after its organization. In these tournaments the shooting, except for flight shooting, was along the lines of traditional target archery, in which the contestants shoot at standard 48-in. targets placed at prescribed distances from the shooting line, the men shooting the York round (72 arrows at 100 yd., 48 arrows at 80 yd. and 24 arrows at 60 yd.), and the American round (30 arrows at each of the distances 60 yd., 50 yd. and 40 yd.), the women shooting the National round (48 arrows at 60 yd. and 24 arrows at 50 yd.) and the Columbia round (24 arrows at each of the distances 50 yd., 40 yd. and 30 yd.), and those in the Junior division shooting the Junior American round (30 arrows at each of the distances 50 yd., 40 yd. and 30 yd.) and the Columbia round.

Within the decade 1937-46 there developed a widespread interest in field archery, as distinguished from target archery. The term "field archery" in its broadest sense included roving, so-called "archery golf" and hunting, in addition to the competitive event to which the word "field archery" was commonly applied. In this competitive event a plurality of targets, often of varying sizes, were placed at different locations on the field and the competitors proceeded over the course from one target to the next in regular order, shooting at each target in turn. A shooting line was laid out for each target and the distance between the shpoting line and the target varied with different targets.

The interest in field archery grew so rapidly that in 1939 the National Field Archery association was organized, one purpose of which was to determine the field archery championships of the United States each year.

In the championship tournaments of the National Archery association during the decade, new records were repeatedly established, so that the 1946 record in each round was well advanced over what it had been ten years before.

When it was decided to cancel the National Championship tournament in 1942, the National Archery association inaugurated a series of nation-wide contests by mail, which were continued each year thereafter. These contests included a clout shoot, a target shoot and a flight shoot. All of these events were enthusiastically received, and in the 1942 target shoot over 1,000 archers participated.

Ind.

During the war years the competitive events sponsored by the National Field Archery association were in the nature of mail matches. In 1946 this organization held its first annual championship tournament at Allegan, Mich., with 476 field archers participating. In this event the men's field archery championship was won by Erwin C. Pletcher of Bakersfield, Calif., the women's championship by Mrs. H. A. Bitzenburger of Los Angeles, Calif., the junior boys' championship by M. LeFavour of Fort Wayne, Ind., and the junior girls' championship by Kathleen Powell of Portland, Ore.

Architecture

Architecture reflects the civilization of an age. Buildings are planned for the needs of a people and are created out of the current thought and spirit of the times.

The contrast in the architectural expressions of buildings during the ten eventful years 1937–46 mirrored the conflict in social ideologies throughout the world. Two fundamental concepts of architecture were opposed to each other—the traditional and the modern. The sway in popularity from one to the other with occasional reversals, the growth of one style and decline of another with some levelling of the clashing contrasts between them showed that the architecture of that period belonged to a world in a time of transition. The motivating forces to change and progress were the diverse movements toward social betterment, the accelerated progress in science and industry and the changing attitudes toward the past.

Traditional Architecture.-The strength of traditional architecture lay in its harmony with the past. It carried on historic styles or evolved its own style along classic principles. The patterns were familiar to the public, and the formulae of designs were the old routine of architects. There was a striving for monumentality and ostentation which found visual appeal with the masses. Symmetry and proportion based on classic discipline suggested order. The residential designs continued the familiar motifs of conventional styles, at times transplanted from the old world to the new or from one region to another. The outward characteristics were those derived from masonry architecture: solid-appearing walls with small windows and doors; surfaces broken by cornices, columns, pilasters and ornamentation. The interiors were rigidly enclosed by architectural treatment that carried around the enclosing walls to tie in the fenestration. Machine production was used to imitate the work of old craftsmen. Functional and utilitarian requirements gave way to the dictates of styles.

The national styles of the U.S.S.R., Germany and Italy were all traditional in that historic forms and classic doctrines were used in their designs. In this category also belonged the various eclectic styles, neo-romantic, neoclassic, and Neo-Gothic, which applied the motifs of traditional styles with modifications suited to the taste of the times and place of building.

Modern Architecture.—Modern architecture was not a style, but a new concept of design which stood for a rational approach to contemporary building problems. It strove for honesty in the expression of functional requirements, for achievement in construction, for utilization of new processes of building and modern materials offered by industrial and scientific progress.

From an aesthetic point of view, modern architecture concerned itself foremost with the design of space in contrast to the traditional emphasis on façades. The modern approach attacked the shaping of a building from the inside out. Thus, the modern concept gave a new freedom to design; neither the dictates of obsolete systems of construction nor the rules for traditional design derived from them were permitted to interfere in the shaping of the spaces. Steel, concrete, or wood framing, particularly the use of skeletons of columns supporting girders and floor

or roof beams, allowed the insertion of walls at will. The fusion of rooms by the elimination of unessential dividing walls resulted in the "open plan." The phrase, "bringing the landscape into the house" referred to the use of sheets of glass in place of exterior walls for the purpose of a merger between the outdoor and indoor spaces.

Simplicity and a functionally honest design expression, combined with an absence of ostentation and ornamentation, were the apparent characteristics of modern architecture. The design forms were distinguishable by their building masses of cubes or prisms, often interpenetrating; by plain and thin enclosing walls with large areas of glass. The roofs were commonly flat or slightly pitched in one or two directions.

"Functional architecture" was the name most commonly given to the style of design resulting from the modern concept. Frank Lloyd Wright, striving for a fuller expression of all phases of design and placing greater emphasis on aesthetics and the interpretation of life in art, identified his own work as "organic design." The name "international style" was given to the early forms of modern architecture which appeared with identical characteristics throughout the world. "Regional styles," in contrast thereto, adjusted the modern characteristics to the climate, the building materials and the habits of people in various regions.

The "modernistic style" had nothing in common with modern architecture, but was often confused with it. It represented a decorative approach to design traditional in basic concept, which used great abandon in the application of motifs devoid of classic discipline (bay or corner windows, etc.) and ornament of bizarre forms.

History of the Modern Movement.—The dawn of a new architectural concept had come in Europe with the beginning of the 20th century. The movement toward a new architecture was foreshadowed in the works of isolated architects—in the United States, Louis Sullivan and Frank Lloyd Wright; in Belgium, Henri Van de Velde; in Germany, Peter Behrens, Joseph Olbrich and others; in Autria, Otto Wagner and Adolf Loos; in France, Auguste Perret. The spirit behind these scattered attempts to break with the rigid codes of historic styles kindled the flames of revolt.

This architectural revolution had burst forth after World War I. The calamity of destruction resulting from the strife between nations had shaken the faith in the past. Reigning dynasties had been abolished and a new social consciousness had been aroused. The Industrial Revolution had progressed to the point at which machines had vastly influenced daily life and the technique of building. Thus opportunities to the rise of new thought and experimentation were opened. This new spirit fanned the sparks of revolution into a movement toward a new architecture. The most pronounced agitation for an architectural revolution appeared in the Vers une Architecture (1924), of Le Corbusier (Charles Edouard Jeanneret). In Germany, the movement entered into the teaching of architecture and allied arts at the Bauhaus (in Weimar and later in Dessau) founded by Walter Gropius. Architects from many countries united for the promotion and development of modern architecture.

This new architecture had its roots in social and economic changes. The concern of architects for social betterment supplanted the previous interest in providing for luxury and wealth. Housing, buildings for health and welfare and recreation became of tremendous importance.

Frank Lloyd Wright, in common with the pioneers of the new movement of Europe, attacked outworn architectural conventions. To him, romanticism in art expressed liberation from the dogmas of the styles of the past. Arguing against functionalism, he expressed the belief that all great architecture must transcend in its visual form the expression of practical necessities, and that a functional solution of a building problem must become merely the framework to the artistic creation. He was not a logician but a poet, yet through intuition and feeling he produced a fusion between analytical experiment and invention.

Le Corbusier called architecture "the aesthetics of engineering." He argued that architecture was in an unhappy state of retrogression, the old architectural styles having lost their reason for existence with the rise of a new style of steel and concrete. This change to him signified the revolution in architecture. Walter Gropius, in his Theory and Organization of the Bauhaus, published in 1923, pointed to the devitalizing influence of the academies of art and sought in his approach to design the basis for a reunion between the creative artists and the industrial world.

Transition.—The international expositions of 1937 and 1939 served as a record of architectural thought in the various countries. They provided an opportunity to display the new and to represent the work of the outstanding talent among different nations. For these reasons an interesting demonstration of the conflicting ideologies and approaches to architectural design appeared, first at the Paris International exposition of 1937 and later at the New York exposition of 1939.

The Paris exposition presented a representative cross section of national trends in architecture. It was interesting to note that the national pavilions of the U.S.S.R. and Germany achieved an almost identical effect of aggressive, massive force. The German building adapted classic modes to its own ends. The Russian building was a streamlined pedestal for a gigantic statue of two workers.

In the New York exposition of 1939, several other ideologies appeared. The U.S. buildings showed the influences of advertising and display technique on architecture. The pavilion of France reflected the fondness for decoration typical of the French people, and also an unfortunate decline to an artistic confusion. In contrast thereto, Brazil's modern pavilion portrayed a fresh spirit, and the smaller countries, Sweden and Finland, were represented by architecturally distinguished buildings indicating a native strength in design.

The nationalistic ideologies of the totalitarian countries in Europe reflected themselves in an establishment of national styles. The Russian, German and later the Italian governments exercised direct control over architectural designs. Modern architecture was scorned and forbidden by laws. Architects were robbed of their freedom to design in new forms and to develop further the promising start modernism had in those countries. This resulted in a migration of the most influential proponents of modernism to the democracies.

In Germany, Italy and the soviet union, propaganda architecture was important and provided forums for mass meetings and striking architectural decorations for state visits. Military architecture produced defense lines, and theories on bomb-proofing for towns and buildings were tested. Preparation for war became noticeable. In England and the United States, the progress of modern architecture was accelerated by the modernists from the totalitarian countries who found refuge there.

The beginning of war in Europe in the fall of 1939 arrested all normal architectural progress on the continent and in England. In the latter country, the growth of the

new architecture continued for a while, motivated by the influences of the newly arrived European architects. The year 1940 will be remembered for the beginning of the wanton destruction of architecture by aerial bombardment. The German invasion of France disrupted the artistic influence of that country. No longer was it possible for foreigners to go to the École des Beaux Arts in Paris for study. The American School of Art at Fontainebleau was closed. The French, English and American academies in Rome gradually shut their doors, ending at least for the time being the classic influence on architectural education. Only in the Americas, Palestine or the colonies did European influences contrive to be felt through the activities of refugees. By 1940, with the U.S. absorbed in lend-lease production and defense preparations, a period of important architectural development which had extended between two wars approached its end. After the United States entered World War II in 1941, practically all building activities throughout the world were devoted to the needs of the armed forces, the production of war materials, the housing of war workers, and the most urgent requirements for the safety, health and welfare of the civilian populations. Only the Latin American countries continued to carry on sufficient building to prolong the progress in modern architecture.

The architecture during the World War II period became utilitarian in character. Its visual form grew out of the temporary nature of buildings designed for the duration of the war, out of shortages in materials and manpower, and out of the speed and efficiency demanded by the war effort. As the war progressed into 1942, 1943 and 1944, postwar planning received ever-increasing attention. It had become necessary to plan for, and to demonstrate through public exhibitions, the opportunities for better living that could be created in peacetime. Likewise, it was important to prepare plans for the absorption of manpower that would be released by the end of the war. The new concept that architecture could serve society by aiding in the planning of a better world took hold. A profusion of plans for towns and regions were made; official reports, literature, propaganda pamphlets, advertisements and exhibitions of postwar proposals appeared. Progress in architecture took place on paper.

The first postwar months in 1945 and 1946 brought little encouragement for actual building. The effects of the global strife were too great to permit the immediate return to normalcy in architectural practice. The problems of readjustment in the dislocations resulting from the war, material and manpower shortages, combined with a considerable rise in construction costs, delayed the execution of most projects. The accumulation of blueprints prepared in the war years as an aid to re-employment during demobilization remained temporarily unused. While building activity in the U.S. and the neutral countries was delayed by these knotty problems of reconversion, the warring countries of Europe and the orient suffered from so large a destruction and disruption that all building other than that of an emergency nature remained at a standstill. The great immediate need was housing and emergency repairs of the damages of war to make conditions of life bearable.

Planning and Design.—A scientific attack of the problems arising in building design supplanted the emotional approach. Building plans were dictated by functional requirements which, in turn, governed the aesthetic form. Architects were called on to delve deeper into the needs

of their clients to provide for the most efficient operation of the building they were designing. Their attention was focused on the improvement of working and living conditions. The basic requirements of the human being for health and comfort were analyzed. Space demands for many building types were calculated; cost, rent and income studies commonly preceded the preparation of the construction drawings.

Looking toward a new era of building, architectural periodicals and popular magazines devoted much space to the comfort and luxuries possible in postwar houses. "The Houses of Tomorrow," as they were commonly called in U.S. books and exhibits, featured glass-walled living spaces, elaborately built-in storage provisions, richly appointed kitchens with a multitude of labour-saving devices, and a variety of extravagant installations for television receivers and moving picture displays and so forth. In the design of housing for workers, low cost was mandatory. Toward this requirement, dwelling units were reduced to smaller but efficient sizes, and mass production processes were employed in construction. Housing became a separate fieldin which the co-operation of town planners, sociologists, experts in government, finance and construction was demanded. (See Housing; Town and Regional Planning.)

Public schools, kindergartens and nurseries and other educational facilities were greatly influenced by the progress in educational methods. Greater flexibility in educational structures to permit periodic changes in educational programs became evident. Daylight, artificial illumination and the acoustic properties in school buildings were improved. The demand for interior space in U.S. schools was greatly increased by a need for the enlargement of the school lunchroom facilities and a fuller athletic program. The school grounds were extended to provide more play space, parking facilities and better planting.

Commercial buildings were designed to bring a high return in rental. Office buildings provided for a greater variety of rental space, following the principle established at Rockefeller centre in New York, where restaurants, theatres, garages, exhibition spaces, shops and broadcasting studios were combined into a successful operating entity. Stores were greatly aided in their design by the development of unbreakable glass. Metal and wood, which formerly had to be used in the doors and for the support of the show windows, were eliminated. The show window, which was previously a narrow strip of display space blocked off from the store, disappeared and the entire store was converted into the display area.

In theatre design, the era of the gigantic motion picture houses ended in 1930 with the construction of the Rockefeller centre theatre of 6,000-seat capacity. Thereafter, greater emphasis was placed on the building of smaller and more intimate neighbourhood theatres, particularly where parking facilities as an integral part of the theatre property were feasible. Plans were made for prefabricated motion picture houses which could be produced in the U.S. and shipped to various parts of the world. Progress in mechanical devices, in lighting and acoustics, allowed unusual flexibility in the design of theatres for plays and spectacles. The stage house and the auditorium could be enlarged or changed at will by movable walls, and rising, lowering and revolving floor sections. The application of such ingenious devices in modern theatre planning was demonstrated at a theatre in Malmoe, Sweden. Invariably the shape of the auditorium was determined out of a study of acoustic properties and sight lines.

In industrial architecture, the one-story factory established itself as the prevalent type, following the manufacturers' desire for large, clear floor areas unobstructed by columns, stairs or elevators. Buildings allowed for the proper "flow" in production and the changes demanded for retooling or the shift to new products. Windowless as well as daylight plants were built. Progress in fluorescent lighting and air conditioning made the design of windowless factory buildings practicable. Under the consideration of wartime blackouts, night shifts and the heating effects of solar radiation through glass areas, this type had many advantages to offset its increased initial expense, but met with psychological objections from the workers. Toward the end of World War II, more industrial buildings were designed as semi-daylight plants, in which just sufficient windows were incorporated to provide a visual contact with the out-of-doors. Workers' comfort received greater consideration. Recreation rooms, more spacious locker rooms and attractive cafeterias were provided.

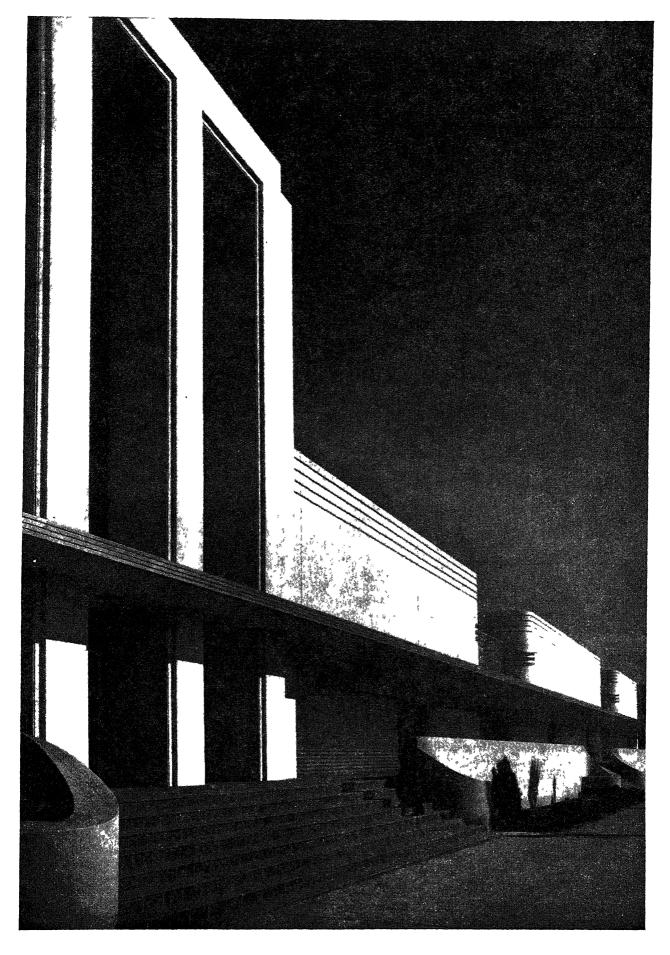

Medical institutions took on a new significance in architecture with a growing emphasis on social betterment. They ranged in size from small neighbourhood health clinics to average city hospitals and large health centres. The latter grew to unprecedented capacity, providing elaborate facilities for the treatment of patients numbering up to 3,000 and over. While fireproof materials were still available, multistory construction with centralized kitchens established itself as the prevalent type. During the war, while the demand for hospital facilities greatly increased, steel and concrete were harder to obtain and it became necessary to return to the pavilion-type plan, which resulted in buildings of nonfireproof construction one or two stories high, spread over large tracts of land. The extraordinary progress in medicine and surgery demanded substantial changes in hospital planning to permit the application of epoch-making discoveries under the best possible conditions.

Techniques and Materials.-Over a period of time, building processes had shifted from the building site to the factory. First timber came pre-sawn; later, finished doors and windows were obtainable. Finally, the continuing progress in building technique caused the reduction of field work solely to site preparation, foundations and assembly of factory-built parts. This was first accomplished in small-house construction, and then in school buildings and other larger structures. Prefabricated wall, floor and roof panels, partitions, stairs, etc., were commonly used. Assembly of prefabricated parts also allowed demountability, thus making possible internal changes, enlargement and relocation of buildings with a minimum of waste. Shop fabrication demanded a standardization of measures for the various components of buildings. A modulus of 10 cm. was used as the basic measure in Russia, and 4 in. as basis to the dimensioning of building materials in the U.S.

Throughout construction existed a trend to reduce weight. In steel construction this was made possible by welding, in concrete by prestressing reinforcing bars, in wood by laminating of thin members into beams and girders, or by the use of metal connectors between light timbers.

The development of new materials resulted from efforts

Modernism in architecture resolved itself during the years preceding World War II into functionalism both in design and in materials used. Excess details were eliminated and the decorative element made a part of the structural pattern itself. The NBC studios in Hollywood, Calif., represent the transition from the decorative façades typical of the Beaux-Arts school of Paris to true modernism

to reduce the cost of construction through savings in labour costs; from a search for cheaper substitutes for the older building materials; and from a demand for new decorative treatments. Plywood became a prominent new material which was used for interior and exterior wall surfaces, and for a vast range of decorative and structural purposes. It was glued to timber to carry stresses (skinstressed plywood construction). The development of twodirectional bending of plywood for aeroplanes brought moulded plywood surfaces to building and furniture making. Resin bonding agents rendered plywood waterproof, making exterior application possible. A vast variety of wallboards served as new surface coverings, substituting for plaster and permitting dry construction. The latter allowed the acceleration of the construction process and facilitated prefabrication of wall and ceiling panels. Development of new adhesives and various compounds to assure the tightness of walls and roofs allowed simplification in the methods of construction. Paints, preservatives, fireproofing agents for wood, as well as new waterproofing compounds, signalized profound changes. A great variety of new insulants made the thin and light wall and roof construction possible. Glass underwent profound changes. Through heat treatment it was rendered unbreakable for use in doors and furniture. By the addition of chemical substances the penetration of heat rays through window glass was combated. A spongelike material of unusual lightness in weight and great rigidity, known as foam glass, was developed for insulation purposes, along with a whole variety of glass wools.

In the field of building equipment, fluorescent lighting constituted the most important change after the invention of the filament lamp. The heating of buildings through warmed floors and walls, known as "panel heating" or "radiant heating," was increasingly accepted in design.

An ever-increasing number of mechanical conveniences were developed which played a large role in adding to the comfort and reducing labour in the homes. Prominent among the new appliances were cooling units, food freezers, automatic laundry equipment, automatic control devices for heating, air cooling, air cleaning and humidification. Industry revolutionized the designs of kitchens and bathrooms. Prefabricated units for both of these rooms came into use.

Architectural practice underwent corresponding changes. The great complexity of the planning and design process demanded the co-operation of specialists in the fields of architectural design, structural and mechanical engineering, cost estimating, etc. The mechanical installations for heating, ventilating, sanitary equipment, illumination and acoustics became increasingly intricate and costly. The architect's position was that of a co-ordinator. A large amount of drafting and detailing was required to convey the quantity of intricate information demanded for the industrial production of the building parts formerly cut and fitted on the construction site.

The war demanded that construction of industrial plants and military installation proceed with unusual speed. Factories as large as 35 ac. were planned and built in the U.S. in as little as three months. Germany and the U.S.S.R. likewise carried out gigantic projects in record time. This resulted in a concentration of a great number of specialists and technicians in one office, and the rise of larger organizations and huge architectural bureaus of governments. Governmental regulation and standardization were on the increase.

Architecture in Great Britain.—An important architectural advance in England in 1937 was demonstrated by the apartments at Highgate, London. These were functional in plan, modern in construction and design. In 1938, Highpoint No. 2 was built at Highgate (Tecton, architects), which showed the same modern functionalism but with a greater concern for decoration. Throughout the country, unusually large medical institutions came into existence, such as the Birmingham Hospitals centre. These showed a universal preference for high buildings in contrast to isolated pavilions.

The British Empire exhibition at Glasgow, Scotland, followed the modern design trend and in several buildings echoed the Paris exposition of 1937, and as an example of architecture along traditional lines there arose the new and imposing city hall of Norwich.

In 1939, the Health centre for the borough of Finsbury, by Tecton, showed the part architecture had begun to play in the organization of social services. The expression of a modern social need was also given in the Impington Village college of Cambridgeshire, Walter Gropius and Maxwell Fry, architects. For official architecture, traditional designs were preferred, demonstrated by the new government building of Edinburgh (Thomas S. Tait, architect) and the town hall at Wolverhampton (E. D. Lyons and L. Israel, architects).

During the blitz, air-raid precautions became of major concern to architects. Efforts were directed toward camouflage, protection against damage from bombing and erection of evacuation camps for children. Some buildings planned for social needs before the war were completed, such as nurses' homes, health clinics, a working-girls' club and sport pavilions.

Through 1941, architects in private practice were engaged in the construction of hospitals, hostels, camps, stores, etc., the development of air-raid shelter schemes and government buildings. They reported on air-raid damage and advised on the safeguarding of historic buildings.

In 1942, attention was drawn to a master plan prepared for the rebuilding of London by the Modern Architectural Research society (M.A.R.S. group), and later to pictorial illustrations accompanying the designs for the future capital of the empire by Sir Edwin Lutyens, architect, and Sir Charles Bressey, planner, prepared under the sponsorship of the Royal academy.

The architectural activity of 1943 was primarily devoted to further plans for the rebuilding of Great Britain. The County of London plan, prepared by J. H. Forshaw and P. Abercrombie at the request of Lord Reith, minister of works, proposed a 50-year program aimed at the repair of war damage combined with improvements to obsolescence, bad and unsuitable housing, inchoate communities, uncorrelated road systems, industrial congestion, low level of urban design, inequality in the distribution of open spaces and increasing congestion. The plan for the reconstruction of Coventry also aimed to create order out of disorder and destruction.

A temporary quality of design which war necessity gave to architecture was shown in a hostel for British war workers, F. R. S. Yorke, architect. Public buildings were expressed in classic monumentality with motifs somewhat influenced by Swedish architecture.

In 1944, England suffered another period of devastating bombing by the V-1 and V-2 bombs. This resulted in more destruction of buildings, with a great loss of homes. Thus in 1945, with the return to peace, private building enterprise and public effort joined in an effective working partnership to meet the urgent housing needs. The new

Labour government viewed the temporary housing construction with considerable disfavour, and based its future policy on plans to concentrate all energies on permanent housing.

United States.—In 1937 and 1938, a good deal of building was in progress, such as the Rockefeller apartments in New York city and the Williamsburg housing project in Brooklyn, N.Y. Many of the European architects had already arrived in the U.S. to teach and practice architecture in the east and middle west. The influence of Walter Gropius and Miees Van der Rohe was beginning to be felt in architectural education and practice. Greater acclaim had come to the U.S. architect, Frank Lloyd Wright. He had risen to new heights in his residential building, "Falling Water," at Bear Run, Pa., and the S. C. Johnson company building at Racine, Wis.

The procurement division of the treasury department was engaged in the design and execution of an unusually large number of public buildings. Unit Plans, a publication of the U.S. Housing authority, established housing standards. A controversy between modernism and traditionalism flared up over the classic design for the Jefferson memorial at Washington, D.C. The following year the New York World's fair and the San Francisco Golden Gate International exposition were held. These two expositions showed the influence of business and industry on U.S. architecture through a profusion of commercial exhibits.

In the residential field, the modern houses of Frank Lloyd Wright, William Lescaze, Richard Neutra and Walter Gropius aroused interest. The building for the Museum of Modern Art in New York showed functional theories applied to U.S. conditions. The winning design, submitted by Eliel and Eero Saarinen, J. Robert F. Swanson, associates, in a competition for the Smithsonian institution in Washington, D.C., stood in contrast to the traditional architecture seen previously in government buildings.

In 1940, architectural development was more or less carried on alone by the U.S. The New York World's fair went into its second year, adding some new installations and showing interiors of modern homes which had found popularity surprising to the traditionalist. The battle between modern and traditional architecture was kept alive by comparative displays in an exhibition entitled "Versus," held at the Architectural league in New York. The premise that buildings are integral parts of communities and that architectural design does not stop with the walls of a building was shown in theory in the exhibition "Telesis" at the San Francisco Museum of Art, and in practice by the parkways, parks, bathing beaches, bridges and tunnels executed in New York under the direction of Commissioner Robert Moses.

The role of the automobile in modern living conditions was taken into account and parking provisions were incorporated. For example, parking was provided on the roof of a store building for Sears Roebuck and Co., at Los Angeles, Calif., John S. Redden, architect and John G. Raben, designer, and a church was proposed for Kansas City, Mo., by Frank Lloyd Wright, with space for automobiles on several levels. A clear expression to functional requirements was also seen in the Lake County Tuberculosis sanatorium at Waukegan, Ill., William A. Ganster, W. L. Pereira, architects.

By 1941, construction contracts had indicated the largest volume of building for any year after 1929. This was, however, limited to the fields of military construction, industrial building and housing for defense workers. The housing project at Indian Head, Md., was built with an

eye to experimentation and demonstration of prefabrication for future residential buildings. At Grand Prairie, Tex., demonstration showed that an entire building could be erected and completed on the site in one day. Houses of cylindrical and domed forms were proposed as new answers to the problems of prefabrication and low-cost housing. Buckminster Fuller showed how a mass-produced steel grain bin could be converted into a demountable house. Independent practising architects were given the opportunity to design dwelling units for workers in defense industries. The size of these projects ranged from 20 to several thousand family units. One of the largest of these projects was at Vallejo, Calif., William Wurster, architect.

The U.S. entry into World War II caused war construction to increase tremendously in 1942. In Washington, D.C., the army engineers completed the Pentagon building, a five-story structure of unprecedented extent, providing 4,000,000 sq.ft. of office space. The Willow Run bomber plant of the Ford Motor company in Michigan, Albert Kahn, associated architects and engineers, became one of the largest industrial projects undertaken during the war. The Austin company built a bomber plant of gigantic dimensions, with wall and roof surfaces lined with a material which accomplished both thermal insulation and sound absorption.

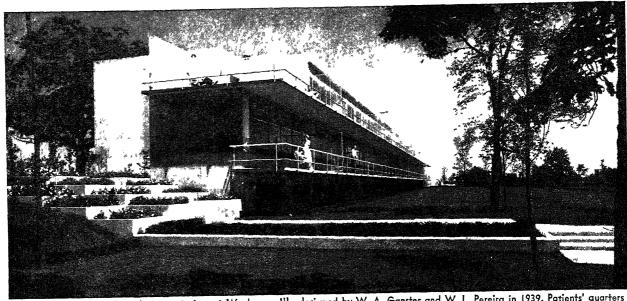

Housing for war workers consisted not only of dwellings but also of community buildings for administration and recreation, stores, schools, etc. School buildings were prefabricated for Federal Works administration projects at Carquinez Heights, Vallejo, Calif., and at Pacific Beach, San Diego, Calif., Franklin and Kump, architects.

Stringent governmental control in 1943 permitted the building of only the most necessary war plants, housing for war workers, construction for military needs and the erection of other buildings essential to the safety and welfare of the public. Housing for workers at the Ford bomber plant at Willow Run was solved by trailers, prefabricated single and multiple-family houses and dormitories.

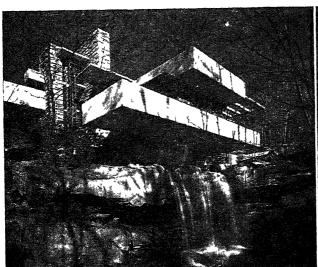

As a result of the steel shortage, the welfare building at the naval training station at Great Lakes, Ill., Skidmore, Owings and Merrill, architects, used laminated wood beams for long spans. A new trend in development in hotel design was exhibited by the Statler hotel in Washington, D.C., Holabird and Root, A. R. Clas, associated architects. In this building, the public lobby was broken up into a series of intimate spaces and segregated into the functions of lounging, transaction of hotel business and circulation. The guest rooms were furnished in the character of living rooms.

The house of John B. Nesbitt at Brentwood, Calif., Richard Neutra, architect, was indicative of a trend of departure from the severe character of the earlier functional style of architecture. A certain artistic freedom akin to poetry was introduced into modern architecture.

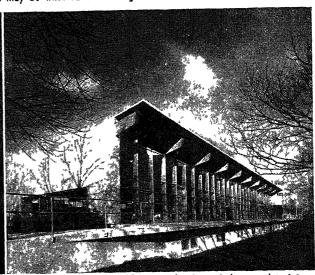

By 1944, plans for postwar buildings were under way. In New York, the city held an exhibition showing its future building program, and an exhibit entitled "Art in Progress" was held at the Museum of Modern Art. The functional requirements of industrial building resulted in a modern expression. Fenestration, which had been omitted in various war plants, reappeared in the U.S. naval ordnance corps at Forest Park, Ill., Albert Kahn, associated architects and engineers, and in the Fontana Steel Mill in California, as the realization grew that some

windows appeared to be necessary to satisfy the workers. The Kaiser Portland shipyards provided a child service centre, Wolff and Phillipps, architects. Large hospitals were built throughout the country to serve the war needs, as for example, the 3,000-bed Halloran General hospital at Staten Island, N.Y.

Projects for the reconstruction or rehabilitation of urban areas were exhibited and developed in Portland, Ore., San Francisco, Calif., and St. Louis, Mo., while Boston, Mass., held a contest for a master program to promote the sound growth and prosperity of the metropolitan area.

By 1945, more projects for urban rehabilitation and housing appeared. The Metropolitan Life Insurance company proposed to finance housing construction on a large scale, aiming to become landlord to 80,000 New Yorkers. The newspapers carried advertisements offering complete prefabricated houses for sale by department stores. General Motors proposed to erect a "City of Science and Art," Saarinen and Swanson, architects.

Frank Lloyd Wright displayed a model for a building to house Solomon Guggenheim's collection of nonobjective paintings in New York city in which he used a spiral ramp as exhibition gallery.

Italy.—Italy was using architecture for the glorification of the state and the fascist ideal. In 1937, the competition for the Casa Littoria, at the Foro Mussolini in Rome, aimed to establish a national Italian architecture. This effort suggested a return to traditionalism. The railway station at Florence was strictly functional in plan, construction and concept, but permitted a monumentalism, a true continuation of the grand manner typical of Italian architecture. In 1938, there still appeared several examples of modern architecture: the buildings at the airport in Milan, Luigi Giordani, architect; a seashore colony for the fascist youth organization, A.G.I.P., and several schools and kindergartens.

In 1940, Italy was engaged in the preparation of a world's fair for 1942, in combination with ambitious plans for the beautification of Rome. Some buildings of the exposition were completed and a large amount of materials for the remainder was on hand at the beginning of the war. Traditional motifs were used, inspired by the architecture of imperial Rome and in keeping with nationalistic tendencies. (The exposition was never held.)

In 1944, Italy suffered from bomb destruction and lost some of its historic monuments such as the monastery and town of Cassino, the bridges of Florence and the Campo Santo at Pisa.

France.—In 1937, the much-renowned Paris fair was opened. The permanent buildings, the Trocadéro and the palace of modern art, were of interest. The Trocadéro was classic in its proportions and symmetry, while in the palace of modern art regard for axial balance was not stressed as much.

During that period, medical institutions of a size exceeding the U.S. prototypes were completed. (The hospitals, Louis Pasteur at Colmar with 740 beds, and Beaujon at Clichy with 1,100 beds, and the Cité Hospitalière at Lille with 4,800 beds.) Throughout all French work a native fondness for decoration was apparent.

In 1938, the influence of the doctrines of the Ecole des Beaux-Arts was still evident in the typical official architecture exemplified by the Museum of Public Works, A. and G. Perret, architects, the French legation in Belgrade, R. H. Expert, architect, and the French pavilion at the New York World's fair, by the same architect.

During the next few years normal building was static in France because of the war and the German occupation. The Allied invasion in 1944 and the bombing preceding it resulted in the destruction of towns, buildings, bridges and the transportation network. Bitter and prolonged fighting annihilated much in the mediaeval and Renaissance towns of Normandy and Brittany.

With peace, in 1945, reconstruction could be planned and the modern architect, Le Corbusier, was chosen by the ministry of reconstruction to serve on a supreme council of city planning in guiding public works. He prepared a plan for the rebuilding of the town of St. Die which was given official approval.

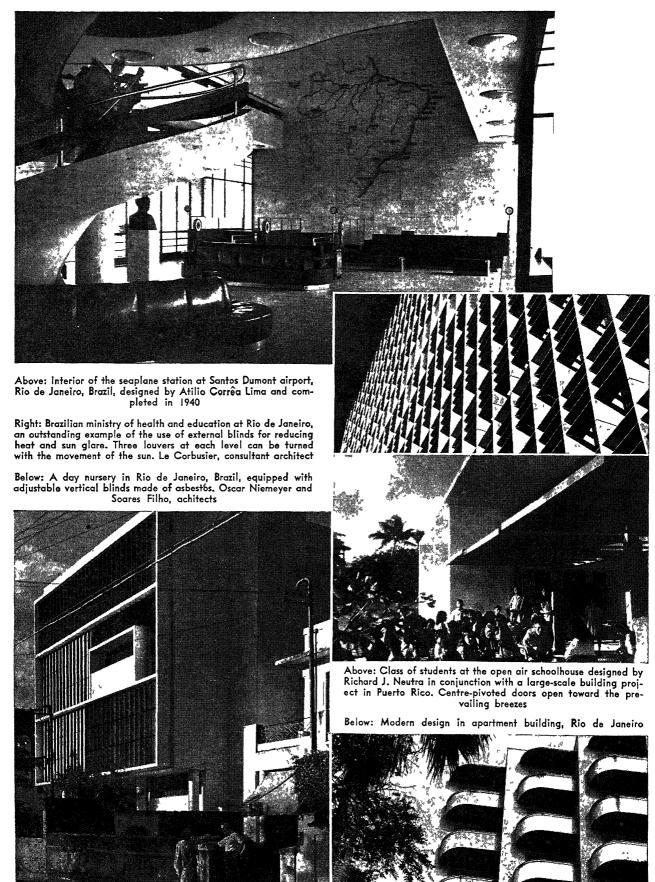

Germany.-In 1937, Germany was in the process of executing projects of a magnitude not seen for centuries on the continent. This architecture expressed the unified and aggressive spirit of the totalitarian state in which organization in the extreme made gigantic tasks possible. The individuality of the architect was denied free expression by rigid style control. The Reichsparteitaggelaende of the National Socialist party in Nuernberg consisted of tribunes for reviews, assembly fields for troops and masses of people, avenues for processions, a congress hall for 40,000 spectators with a stage for 2,400 persons, temporary housing for troops and organizations, a railroad station and a systematic network of roads. The layout stretched over a territory more than 4 mi. long and 2 mi. wide. The recreation buildings and grounds of the organization Kraft durch Freude on the island Ruegen, Clemens Klotz, architect, consisted of vacation dwellings combined with vast squares for festivals, peristyled halls for assemblies and huge swimming pools. The new airport building at the Tempelhof field in Berlin was another example of a large building, superb in system, orderly but dull in design.

In 1938, Germany continued to build in gigantic proportions. Designs for the rebuilding of Berlin were well under way. A main avenue was proposed as a new north-south axis of the city and as a site for government buildings. A circle of huge buildings neared completion before the beginning of the war as terminating feature of the axis and as a gateway to the city. In Munich, the Koenigplatz was reshaped and plans were completed for the rebuilding of the Odeonplatz and the construction of a new opera house seating 2,600 spectators.

In 1940, the Reichskanzlei in Berlin was brought to completion. It was one of the most grandiose and the last important example of national socialist architecture to be finished before the terrific onslaught of World War II. During that same period, a building for the flag regiment of the air force best illustrated the expense and careful planning which typified German military preparations.

From 1941 until 1945, the end of the war, Germany received greater and greater bombing devastation until many of its cities lay in rubble and dust, and numerous ambitious buildings erected by the nazis, as well as much of the old architecture were reduced to ruins. Precision bombing saved Cologne cathedral, but many of the fine old buildings and squares of many towns famous for their beauty, like Nuernberg and Dresden, were destroyed.

U.S.S.R.—In 1938, the soviet union reverted to traditional classicism for its new national architecture. Moscow's All Union Agricultural exposition paradoxically used porticos and columns associated with imperial Rome. The Club of Moscow showed, like most soviet architecture, an equal fondness for classic pomp. There existed a vogue for the placing of gigantic statues on the top of buildings which started with the design of the palace of the soviets and continued in many official buildings in the U.S.S.R.

as well as on the soviet pavilions in the expositions of Paris and New York.

The manufacture of houses was studied and developed by the Institute of Construction Technique, a department of the Academy of Architecture. Despite advanced prefabrication methods, traditional colour and ornate detailing was still much in evidence in small-house design. The government encouraged the development of local building materials, concentrating on brick, stone, rubble and timber, and the manufacture of artificial stones and building blocks from cement, plaster, gypsum, compressed grasses or weeds.

The organization of the profession of architecture and the building industry was carried to the extreme. The state direction of all architectural activities was vested in the Committee for Architectural Affairs under the council of ministers. The Academy of Architecture controlled the practice of the profession and had for its main purpose the improvement of standards, the study of theoretical and historical background, the advancement of planning and construction, and the training of architects and scientific workers Typical of the traditional education, the history of architecture was a major subject of study.

Smaller European Countries.—Notable contributions came to architecture from the smaller countries of Europe, where a reasonable economic stability and continuing progress in social improvements combined to provide a fertile soil for a healthy progress in architecture.

Sweden had changed from classicism to modern ideas in the early 1920s. After some experimentation with national romantic and neoclassic styles, the country turned to the modern with the Stockholm exhibition of 1930. A delicacy of form and an expression of the fine qualities of native folk art combined to achieve distinction in the work of Swedish architects, among whom Gunnar Asplund was outstanding

Swedish school buildings were distinguished for their functional interpretation of the educational and spiritual needs of children. Swedish housing was outstanding for the demonstration of the truly democratic way of living. The manufacture of prefabricated timber dwellings had grown to an extensive industry and contributed much toward the improvement of the country's housing standards. The entertainment centre of Malmoe combined the functions of theatre, opera house and concert hall in a single elaborately equipped structure. The architects (Eric Lallerstedt, Sigurd Lewerentz, David Hellden) produced the ultimate in flexibility in providing four alternate possibilities for dividing the auditorium.

In Finland, the designs of Alvar Aalto typified the functional architectural character of the new way of building. The town of Helsinki built a large, imposing stadium, Yrjoe Lindegren, architect, with a reinforced concrete tower in preparation for the Olympic games of 1940 which World War II prevented.

Switzerland was also dedicated to the modern movement in architecture. This movement was largely influenced by the work of Le Corbusier and Professor Karl Moser of the State University of Technical Science in Zurich. Among the more prominent contributions were the auditorium and convention hall in Zurich, W. M. Moser, R. Steiger and M. E. Haefeli, architects; the Cantonal hospital of Basle, E. and P. Vischer, H. Bauer, B. L. Duerig, architects; and several schools. Many modern apartments were built and residential design in general was distinguished by its native charm.

Other Countries.—In Palestine, South Africa and Australia, examples could be found which in their similarity

to the modern buildings of Europe showed the international acceptance of the modern movement.

Brazil developed a modern architecture peculiarly suited to its local climate and customs. The buildings showed in their designs the influence of Le Corbusier combined with a native character given them by their Brazilian architects. Among outstanding examples were the Instituto de Resseguros at Rio de Janeiro, Marcelo, Milton and Mauricio Roberto, architects, several office buildings with façades consisting of grids of concrete fins for the shading of windows, and the work of the architect, Oscar Niemeyer. (See also Building and Construction Industry.)

Archives, National

At the beginning of the decade 1937–46, the United States National Archives was an infant government agency. Established in June 1934, it had only just begun to transfer to its specially constructed modern building on Constitution avenue between Seventh and Ninth streets in Washington, the permanently valuable noncurrent federal records it had been created to preserve and service. In the next ten years, however, an increasing stream of such records flowed in until by the end of 1946 the archivist of the U.S. had in his custody about 750,000 cubic feet of government records.

These records came from congress, the White House, every executive department, scores of other agencies, and several federal courts. They ranged in date from the Revolutionary War through World War II. Among them were hundreds of millions of handwritten or typewritten documents; about 450,000 maps and charts, of which half were manuscript or annotated; more than 200,000 sound recordings, including recordings of such historic events as the Normandy invasion and of speeches by prominent people; more that 1,300,000 photographs, including such early ones as Mathew Brady's famous Civil War pictures; and some 60,000 reels of motion-picture film, including axis films captured during World War II.

Only a fraction of the records created by federal agencies were deemed worthy of permanent preservation, and one of the jobs of the National Archives was to facilitate the destruction of those of no lasting value. Procedures for disposal were greatly simplified during the decade, and the National Archives undertook a records administration program, which encouraged government agencies to modernize their filing methods, dispose of worthless material promptly, and transfer valuable records to the National Archives as soon as they were no longer needed for day-to-day transactions. This program resulted in better control over current records, in substantial economies of time, equipment and space, and in more valuable records being transferred to the National Archives.

Most of the important older records of the government

were, by the end of 1946, in the National Archives. Many federal agencies, including the war and navy departments, transferred practically all their records up to World War II, and the records of a number of World War II agencies, such as the Office of Censorship, the Office of War Information, the Foreign Broadcast Intelligence service, and the War Relocation authority, had already been received. This wealth of material recorded the experience of the U.S. in war and peace from its earliest days of independence. Such symbols of the long struggle for freedom as the Treaty of Paris in 1783, in which Great Britain recognized the independence of the American colonies, the Bill of Rights, the Emancipation Proclamation, and the German and Japanese surrender documents were among the records in the National Archives. Most permanently valuable federal records, however, were preserved for the information they contained rather than for their symbolic or patriotic character. The major contribution of the National Archives was to make that information available. This it accomplished during the decade through exhibits, a reference service, and description of the records in guides, such as Your Government's Records in the National Archives, in catalogues of exhibits, such as The National Archives of the United States; Catalog of Exhibit and President Roosevelt and International Cooperation for War and Peace, and in documentary publications, such as Germany Surrenders Unconditionally and The End of the War in the Pacific, containing facsimiles of World War II surrender documents.

During the decade, requests for services on records in the National Archives jumped from about 20,000 to as high as 320,000 a year. These requests were filled by supplying information by letter, telephone or personal interview, by preparing studies, by lending records to government agencies, by furnishing photographic copies of documents at cost, and by making records available for use in the searchrooms, open every day except Sunday.

Uses made of federal records were as varied as the records themselves. Scholars, writers, and the public in ever-increasing numbers used records for political, economic, and social studies, for biography, for genealogical research, or to obtain information for the protection of some legal right, such as the right to a pension. Changing events greatly coloured the details of information sought, but the kinds of uses remained much the same. The government usually sought precedents or information for the protection of its legal rights or those of others.

During World War II the government drew upon its own experience in World War I, the records of which were in the National Archives. Information thus obtained saved precious time and helped to avoid mistakes on the administrative front. To guide busy officials to pertinent materials, the National Archives prepared many special studies and published a 666-page Handbook of Federal World War Agencies and Their Records, 1917-21. To assist on the operational side of the war, the National Archives supplied pictures of roads, railway terminals and power plants in Europe and Asia, charts of many a Pacific atoll, and reports of consular and diplomatic representatives on the natural, industrial, and human resources of axis countries. Information about archives in Europe and Asia was furnished so that they might be spared unnecessary bombing and later might be protected and utilized by the occupation authorities. Never before in the history of warfare had soldiers invaded countries armed with such information about the historical and administrative archives of the enemy. With the end of hostilities, the interest in records in the National Archives shifted to those pertaining to reconversion, the rehabilitation of veterans, the disposal of surplus property, and the punishment of war criminals.

In 1936 the National Archives began publication of the daily Federal Register, containing government regulations having public effect. During the war, the Federal Register grew in size and importance as an aid to administration, both governmental and industrial. An administrative procedure act required the publication in the Federal Register of descriptions of the organizations and procedures of all federal agencies and many other documents not previously required to be so published.

The decade saw the establishment, in 1939, of the Franklin D. Roosevelt library at Hyde Park, N.Y., as a government agency under the administration of the archivist of the U.S. The library, designed to house Roosevelt's papers and collections and related materials, opened some of its holdings to searchers in 1946, and thus began to realize its importance as a research centre.

Areas and Populations

The accompanying table presents the area, population and density of population of the various nations of the world, using the latest figures available at the end of the decade 1937–46. Under the postwar conditions of 1946, it was difficult in some instances to secure data which were entirely satisfactory. The figures relate to different dates in different countries. (For population figures at intervals during 1936–47, see specific country.)

†1945 figures used in computing totals.

Argentina

Argentina, second largest nation of South America, extends approximately 2,070 mi. from north to south, with a maximum width of about 860 mi. The area (excluding the Falkland or Malvinas Islands, to which Argentina laid claim) is 1,079,965 sq.mi. Pop. (est. of Dec. 31, 1944), 14,130,871; earlier official estimates of the national population were: 1940, 13,132,279; 1941, 13,320,641; 1943, 13,909,950. The population was estimated to be 97% of European (mostly Spanish and Italian) descent. The total of foreign-born population in 1940 was 2,355,900. An official estimate in 1938 indicated the percentage of urban population to be 74% as against 33% shown by the census

of 1869. Population density for the entire country was estimated Dec. 31, 1943, as 12.96 per sq.mi. The capital is Buenos Aires (pop., 1945 est., 2,608,333; by 1941 municipal census, 2,408,900), the continent's largest city and Argentina's most important port. Other important cities (with official population estimates) are Rosario (521,210), Avellaneda (399,021), Córdoba (339,375), La Plata (256,-378), Tucumán (169,566), Santa Fé (149,926), Bahía Blanca (121,055), Mendoza (100,429) Lomas de Zamora (100,000), Vicente López (95,770), Mar del Plata (94,-500), San Juan (80,000), Paraná (76,600). Under the constitution of 1853 (the oldest in any Latin American state) Argentina included 14 provinces and 9 territories; a decree of Sept. 24, 1943, abolished the territory of Los Andes and divided its area among the three adjoining provinces of Catamarca, Jujuy and Salta. The municipality of Buenos Aires was withdrawn in 1880 from the province of the same name and nationalized as a federal district. The government of Argentina was constitutionally patterned after that of the United States to include a president chosen by a popularly elected electoral college for a six-year term, a bicameral congress composed of a senate of 30 and a chamber of deputies of 158 members, and a judiciary headed by a supreme court. Presidents during the decade 1937–46 were as follows: Gen. Agustín P. Justo, 1932-Feb. 20, 1938; Dr. Roberto M. Ortiz, Feb. 20, 1938-July 3, 1940 (Ortiz surrendered the executive power on that date but did not actually resign the presidency until June 27, 1942); Ramón S. Castillo, July 3, 1940–June 4, 1943; Gen. Arturo Rawson, June 4-6, 1943; Gen. Pedro Pablo Ramírez, June 6, 1943-Feb. 24, 1944; Gen. Edelmiro Farrell, Feb. 24, 1944-June 4, 1946; Gen. Juan Domingo Perón, after June 4, 1946.

The Justo and Ortiz Administrations.-The presidential elections scheduled for Sept. 1937 and the preliminary political activities consequent upon them precluded adoption of much legislation of far-reaching importance when the congress convened May 13. Pres. Justo's general legislative program during his last year in office was to carry forward his policies of previous years. Under them, Argentina had reversed a semi-isolationist policy of some years standing and, under the energetic leadership of Foreign Minister Carlos Saavedra Lamas, had assumed a prominent and aggressive role in international affairs. The domestic policy had in general been a conservative one favouring the powerful landed interests that had been instrumental in electing Justo in 1932 and in the revolution of 1930; some guarded measures of social reform had been introduced, however. In the early weeks of the congressional session of 1937 legislation for land settlement colonization to be financed by the government and for minimum wages, maximum hours and regulation of working conditions was introduced.

On June 23, Dr. Roberto M. Ortiz, minister of finance, and Dr. Ramón S. Castillo, minister of government, resigned their posts to become, respectively, presidential and vice-presidential candidates of the "Concordancia," or government coalition, in the September elections. They represented different wings of the alliance, Ortiz the moderate and Castillo the extreme conservative, and had been chosen to "balance the ticket." The Concordancia was opposed in the campaign by the Radical party, which had been in power from 1916 to 1930, and whose candidate was Dr. Marcelo T. de Alvear, president of the republic from 1922 to 1928. In the September elections, Ortiz won by an electoral vote of 248 to 128 and a popular vote of

Requiem mass at the Buenos Aires cathedral June 12, 1943, for 82 persons killed in Gen. Pedro Ramiřez' coup d'état eight days earlier

1,093,928 to 815,053. The election presumably assured a continuation of the main policies of the Justo regime.

The assassination in April of Josef Riedel, Argentine leader of German nazi activities, in Buenos Aires, aroused strong feelings and caused representations to be made by the German government. Argentina began negotiations with the U.S. during 1937 for a reciprocal trade agreement and during the same year consummated several important commercial treaties. Trade agreements were made with Czechoslovakia, Germany, Italy and the Netherlands. A temporary executive agreement with Peru terminated a serious trade dispute of several years' standing and pointed the way to a definitive treaty. In Feb. 1937 the government signed a tripartite agreement with Bolivia and Para-

guay for the establishment of commissions to develop fur ther trade relations among the three countries. The sen, ate in June ratified eight treaties drafted by the special Inter-American Conference for the Maintenance of Peace which had met at Buenos Aires in Dec. 1936 under the presidency of Saavedra Lamas.

Ortiz was formally inaugurated president on Feb. 20, 1938, for a six-year term. He began a relatively conservative policy characterized by his inaugural declaration against non-American entanglements and in favour of democracy; he also urged strengthening of the national defenses and a continued balanced budget. The congressional elections on March 5, 1938, were generally condemned by the Argentine press as fraudulent, and supplementary elections were held in some districts. Pres. Ortiz thus began a policy of encouraging honest elections, which at times was interpreted as operating to the detriment of his own party. The administration gained a congressional majority in the 1938 elections, so that the government was able to put through its general program without the difficulties experienced in the previous session of the congress.

The new foreign minister, José María Cantilo, conducted a vigorous international policy. He made "good will" tours early in the year to neighbouring Chile, Brazil and Uruguay. The foreign office in April 1938 negotiated an adjustment of a minor boundary dispute with Chile, involving certain Beagle channel islands in the far south of the continent, and provided for submission of the controversy to the arbitration of the attorney general of the U.S. Trade treaties were made during the course of the year with Chile, France and Poland, as well as a barter agreement with Italy, by terms of which Argentine wool and hides were to be traded for Italian-built oil tankers. Public opinion in Argentina expressed itself strongly against nazi Germany, especially after the Munich conference in the fall of 1938, and some efforts to settle Jewish agricultural refugees in Argentina were reported. Foreign Minister Cantilo, however, followed a very restrained policy toward Germany, and at the eighth Pan American conference at Lima, Peru, in December the Argentine delegation led the opposition to a strong stand against totalitarianism. Cantilo was present briefly at the conference but was not a member of the Argentine delegation. Argentina insisted upon mild expressions of Pan American solidarity and was chiefly responsible for a considerable dilution of the resolutions adopted at Lima.

During 1937 Argentina had experienced her greatest prosperity after 1929, as evidenced by the heaviest governmental revenues on record, but poor crop conditions in 1938 resulted in a serious decline in production, a falling off of exports and the tightening of credit. The Argentine peso declined in terms of foreign moneys. Because of the adverse economic conditions, some reductions were made in the 1938 budget, and that budget eventually (in November) was continued for 1939. The government placed considerable stress on public works and on June 28 created a national council of public works. This agency was entrusted with the co-ordination of activities in the 100,-000,000-peso annual program and was charged with regulating construction so that it would be increased during periods of depression and diminished during times of prosperity. Bids and purchases of equipment for the national railways totalling 11,300,000 pesos were made during 1938. Agrarian loans increased to 337,315,227 pesos, the highest sum after 1915. In an effort to aid agricultural prices, restrictions on sugar production were enacted by law, and the government was authorized to set minimum prices on wheat and other commodities. The government spent or

committed itself for the purchase of armaments to the extent of about 90,000,000 pesos during 1938.

Developments in 1939 revolved primarily around the growing threat of war and its later actual outbreak. Publication of documents early in April purporting to reveal sensational German designs on sparsely populated Argentine Patagonia led to a government investigation of the nazi party in Argentina and of other German-influenced groups. The approximately 60,000 Germans and 110,000 persons of German descent in Argentina were in large measure well regimented by German diplomatic representatives and nazi officials and were a factor of concern to the Argentine government. The government on May 15, 1939, issued a decree outlawing all organizations with foreign political leadership or financial support. Italian fascist organizations and the Spanish Falangists, as well as the nazis, were affected. The less effective organization of the Italians (estimated at 780,000 of Italian birth and 2,200,000 of Italian descent) made them of less concern to the government.

The outbreak of World War II on Sept. 1, 1939, brought a prompt declaration of neutrality from the Argentine government. The government participated in the Panama foreign ministers' conference in September-October and assumed a 10le of prominence in the expulsion of the U.S.S.R. from the League of Nations in December. The running engagement of the German pocket-battleship "Graf Spee" off the coast of Uruguay early in December and the subsequent flight of its crew to Argentine waters after they had scuttled the ship following its expulsion from Montevideo harbour, involved Argentina in diplomatic interchanges with Germany, which protested the internment of the sailors. Many of the officers and men later escaped singly or in small groups from Argentine internment, leading in some quarters to charges of laxity in segregating them.

The outstanding feature of the year politically was Pres. Ortiz' campaign for honest elections, which brought him into sharp conflict with the conservative factions that had elected him. Federal intervention (a constitutionally established prerogative of the president) in San Juan and Santiago del Estero provinces early in the year was followed in December by Ortiz' demand that the governor of Catamarca annul fraudulent provincial elections which the Conservative party had won. The situation became politically critical early in 1940 when Vice President Castillo came openly to the support of the governor, and three Conservative members of Ortiz' cabinet resigned in protest.

Foreign trade problems proved of major concern in 1939. As a result of the unfavourable trade balance in 1938, the government adopted a rigid import control policy in Feb. 1939, designed especially to limit imports from countries selling more in Argentina than they bought; the U.S. was especially affected by the policy. Despite official espousal of a multilateral trade system as Argentina's ultimate goal, the government continued its previous policy of bilateral trade treaties; such treaties were made with Denmark and Spain, and most-favourednation agreements with France and Norway. Formal negotiations for a reciprocal trade agreement were reopened with the U.S. in Nov. 1939 to end, if possible, the long period of chaotic trade relations between the two countries. When the war in Europe threatened to cut off Argentina's normal sources of supply, the drastic exchange and import restrictions against U.S. products (the quota had been cut 40% in February) were materially relaxed. Nevertheless, government emphasis was placed on purchases from Great Britain and France. The national public works program was continued throughout 1939, with an authorized expenditure of 200,000,000 pesos in addition to the extensive highway-construction program financed by the imposition of new and the increase of old automotive fuel taxes. The government in 1939 completed the purchase of the Córdoba Central and the Transandine railways, after several years of negotiations, for respective prices of £10,000,000 and £750,000; the latter railway had been closed by landslides in 1934.

Pres. Ortiz formally intervened in Catamarca province on Feb. 19, 1940, to set aside the fraudulent elections earlier held in that province and a few days later took similar action in Buenos Aires province. Interventions in both cases were directed against Conservative provincial administrations, with the result that a political crisis was precipitated; Ortiz was largely deserted by the Conservatives who had elected him and, in effect, went over to the Radical party for support. Congressional elections in March 1940 gave the Radicals control of the lower house of the congress for the first time after the revolution of 1930.

Return to Conservatism.-Pres. Ortiz' serious illness (diabetes and threatened blindness) compelled him to relinquish executive power on July 3, 1940, to Vice-President Castillo and thereby prevented the realization of the full effect of the provincial interventions and the swing of the political pendulum. Castillo was an old-line Conservative entirely out of sympathy with Ortiz' internal policies and reforms. A senate investigating committee precipitated a political scandal in Aug. 1940 by involving the minister of war in a huge land fraud. Ortiz, though bedridden, temporarily resumed office and, declaring the charges to be a personal reflection upon him, tendered his resignation to the congress. The latter body on Aug. 24 rejected it by a vote of 170 to 1. Ortiz then again turned the executive office over to Castillo. A new cabinet composed entirely of moderate Conservatives was organized on

Questions of foreign affairs and war-reflected problems

"The Mysterious Stranger." Argentina's presence among the United Nations as viewed by Daniel Bishop of the St. Louis Star-Times

continued to plague Argentina during 1940. Relations with the U.S. revolved around two major sets of problems-economic and trade difficulties, and hemisphere defense and the general relationship of the hemisphere to the war. The economic difficulties arose from the competitive products of the two countries, especially beef and wheat, and the long-continued unfavourable balance of trade with the U.S.; an additional chronic irritant was U.S. discrimination against importation of Argentine meats because of the presence in Argentina (allegedly magnified as an argument) of hoof and mouth disease. Reciprocal trade negotiations carried on during 1939 were abandoned in Jan. 1940, especially because of strong opposition from cattle-producing sections of the U.S. The foreign exchange problem became increasingly acute when Argentina's purchases from the U.S. doubled during the early months of the year and, in July, Argentina began restricting imports from the U.S. to a point that had virtually reached an embargo by September. U.S. governmental agencies in December, however, advanced credits of \$110,000,000 to Argentina, with \$50,000,000 specifically allocated to currency stabilization.

Problems of hemisphere solidarity as they involved Argentina came into focus at the second foreign ministers' conference at Havana, Cuba, in July 1940. The Argentine delegation, although refusing to assent to some of the more extreme proposals, generally worked in harmony with those from the other American republics. Inasmuch as the main question before the conference was that of the provisional administration of the European colonies in the western hemisphere in the event that nazi Germany should attempt to assume control, Argentina felt an especial concern because of her long-standing though dormant controversy with Great Britain over title to the Falkland Islands. Late in 1940 Argentina made strong protests against a proposed Uruguayan concession of naval base rights to the U.S., although in general Argentina indicated a willingness to join in hemisphere defense plans. The government in July 1940 approved defense appropriations in excess of 1,100,000,000 pesos. The vulnerability of the coast line of more than 1,800 mi. indicated the need for strong emphasis on naval and air defense. The government hence began improvement of naval and aviation bases along the Patagonian coast. High Argentine army officers visited the U.S. in Nov. 1940 on an official inspection trip as part of an inter-American defense program.

The trickle of escapes involving interned crew members of the "Graf Spee" tended to turn Argentine public opinion more and more against the axis in 1940, an effect intensified by the propaganda activities of some of the "Graf Spee" officers. Revelation of the propaganda activities of the nazi-subsidized newspaper El Pampero and of numerous pro-German groups within the country further antagonized public feelings. Much of the activity of German groups centred, especially in the latter part of 1940, in the northeastern territory of Misiones. The government encountered great difficulty in efforts to suppress fifth-column activity there and elsewhere in Argentina.

Sympathy toward Great Britain, on the other hand, continued strong. That country had long been Argentina's best customer and supplier. British purchases of Argentine meats in 1940 reached huge proportions, but full immediate economic return to Argentina was precluded by the British policy of payment in blocked sterling, a practice which brought about an acute shortage of foreign exchange with which Argentina might meet its obligations

elsewhere. An Argentine cattlemen's committee formally offered in Oct. 1940 to restock all visiting British warships with fresh meat free of charge and in December a similar group donated 6,000 head of cattle to the British government. British contracts for foodstuffs, especially meats, for the following 12 months were reported on Oct. 11, 1940, to total between £25,000,000 and £40,000,000. In addition to the continuing close commercial relations with Great Britain, Argentina in 1940 negotiated commercial treaties with Brazil, Colombia and Japan.

Domestic political and economic problems continued troublesome in 1941. The continued incapacity of Pres. Ortiz resulted in political confusion. Ortiz, elected on a Conservative ticket, had veered into a de facto entente with the Radical party, which controlled a majority of the chamber of deputies, but Acting Pres. Castillo proved to be increasingly an ultra-conservative. Tension increased as the year progressed and lessened only with the adjournment of the congress in Oct. 1941. The Radical party, especially because of Ortiz' insistence on enforcement of the "Sáenz Peña law" of 1912 providing for secret voting, viewed the future optimistically and at the beginning of 1941 demanded the annulment of allegedly fraudulent provincial elections in Mendoza province on Dec. 15, 1940, and in Santa Fé province on Jan. 5, 1941. The party adopted an obstructionist policy in the congress and refused to pass essential legislation, hoping in this way to force free-election pledges from Castillo. Only a few bills had been acted upon by May 1941, the budget for the year had not been approved, nor had a recently negotiated \$100,000,000 Export-Import bank loan by the U.S. to Argentina been ratified. When Castillo by executive decree extended the 1940 budget to 1941 and threatened to govern entirely by decree if necessary, the Radical deputies on May 6 ended their legislative boycott. Two prominent cabinet members had resigned the preceding January, reportedly in protest against the acting president's election policy; they were Foreign Minister Julio A. Roca, who had been vice-president under Justo from 1932 to 1938 and was the Argentine negotiator of the famous Roca-Runciman commercial agreement with Great Britain, and Finance Minister Federico Pinedo.

The frequently-negotiated trade agreement with the U.S. was finally signed on Oct. 14, 1941. It provided for reduction of tariff duties by roughly 50% on 84 items which had accounted for 93% of Argentine exports to the U.S. in 1938 and 1939; Argentina in turn reduced her tariff from 25% to 50% on a variety of imports from the U.S. The most important Argentine commodities affected were canned meats, wool, hides, linseed and casein. Although the commercial status of Argentine fresh meat, importation of which into the U.S. had been prohibited after 1927 on grounds that Argentina regarded as insubstantial, was unchanged by the agreement, the general effect of the new arrangement was to remove a major obstacle to hemisphere solidarity. As a result of a Rio de la Plata regional conference in Jan. 1941, Argentina signed a treaty with Brazil on Nov. 21 providing for reciprocal progressive reduction of duties on noncompetitive commodities, tariff exemption of new industrial products, and improvement of communications facilities between the two countries. Other trade treaties were made with Bolivia and Cuba, and negotiations were begun with Chile, Paraguay and Uruguay.

Relations with Chile were somewhat disturbed, however, by the continuance of conflicting territorial claims in the Antarctic; friendly negotiations on the subject failed to produce tangible results. Another question affecting rela-

tions with Chile during 1941 was that of the possible abrogation of a prohibition written into a treaty of 1881 on fortification of the Strait of Magellan; this question was an outgrowth of the new armament and fortification policy of Argentina.

More serious problems of foreign relations grew out of the war. Nazi and fascist propaganda and other activity in Argentina was intensified during 1941. The congress in June aired charges of totalitarian propaganda in the army and of subversive activities in other quarters. Minister of Interior Miguel Culaciatti on June 18 officially admitted, on formal interpellation by the congress, that nazi activities in many directions had become intense, but he belittled their importance. Nevertheless, the chamber of deputies created a committee, headed by Deputy Raúl Damonte Taborda, to investigate "activities contrary to the institutions and sovereignty of the Argentine Republic." The Damonte committee (promptly labelled in the U.S. as "the Argentine Dies committee") was denied administrative and police aid, but it made a sweeping investigation and in August and September presented to the chamber a series of reports with sensational disclosures. The committee asserted that the nazi party, although formally dissolved in Argentina by presidential decree on May 15, 1939, still existed, with an organization on military lines and with the German ambassador directing its activity. German embassy expenditures, it was charged, were 36 times as great (5,983,000 pesos) in the year ending June 30, 1941, as in 1938-39. The German news agency Transocean was revealed to be purely a subsidized propaganda organization with tentacles throughout South America. The reports gave evidence of active axis agents among German schools in Argentina, of German control of 2,000,-000,000 pesos of Argentine business through nazi conquests

An estimated 500,000 Argentine citizens demonstrated in Buenos Aires on Sept. 19, 1945, demanding a return to constitutional democracy and the resignation of Juan D. Perón, then vicepresident. The banner pictures democracy breaking the people's chains in Europe, of a regular system of assessment of Germans resident in Argentina, and of the presence of at least 60,000 nazis in Buenos Aires alone. The committee also revealed the presence of strategically located German groups in Patagonia and the Misiones territory and in other South American countries.

The chamber of deputies, by a vote of 88 to 1, promptly passed a resolution declaring German Ambassador Baron Edmund von Thermann persona non grata and demanding his expulsion. Von Thermann refused voluntarily to withdraw and in September Acting Pres. Castillo formally "dissociated" his administration from the deputies' demand. Further indication of the government's unwillingness to antagonize the axis powers was seen in its cautious policy toward their shipping in Argentine harbours. Argentina refused to follow the lead of the U.S. and other American republics in seizing axis and axis-controlled ships and entered into protracted negotiations with Italy which finally resulted in the purchase of 16 Italian ships totalling 88,000 gross tons to serve as the nucleus of a state-owned merchant marine.

The political situation was suddenly obscured late in Sept. 1941 by infantry occupation of military airports and the grounding of all army planes in what was alleged to be the suppression of a plot. The arbitrariness of the action increased the division between Castillo and the Radicals; a further factor in the same direction was the president's removal, on Oct. 11, 1941, of the Buenos Aires municipal council because of alleged municipal corruption. The Radicals in the congress refused to pass important measures until Castillo pledged free provincial elections in December; the president made no such pledge, however, and the congress adjourned with the split still unresolved. The elections, as anticipated, resulted in a Conservative victory.

War Moves Closer.—Japan's attack on Pearl Harbor on Dec. 7, 1941, compelled Argentina to assume a more posi-

tive position toward the war. Castillo promptly declared that the U.S. would be treated as a nonbelligerent, and on Dec. 16 he declared a state of siege (martial law), accompanied by a suspension of constitutional guarantees, throughout Argentina. Castillo's opponents declared that the action was designed, at least in part, to facilitate his control of the domestic political situation. Newspapers were forbidden to print anything affecting Argentine neutrality or offensive to the government, the political regime, the head of the state, or officials of any belligerent nation. Demonstrations, whether pro- or anti-axis, were prohibited. The press and public opinion were strongly and openly anti-axis, however. Castillo in December recalled the Argentine ambassador from Berlin for "consultation" and on the last day of 1941 he made a formal declaration of Argentine solidarity with the U.S.

Difficulties arising out of the closer involvement in the war continued to affect Argentina in 1942. German submarines attacked two Argentine ships in the first half of the year, thereby lending force to the opposition's bitter criticism of Castillo's neutrality. The "Victoria" was damaged off the North American coast on April 17 and after a secret investigation by the Argentine foreign office it was announced that the damage was accidental and was caused by "an internal explosion of undetermined origin," but on June 17 the foreign office reported receipt of a nazi apology for the attack upon the vessel. The "Rio Tercero" was sunk on June 22 only 120 miles off New York city; the Argentine government on June 26 made a vigorous protest to Germany, calling for the payment of damages, a salute to the Argentine flag, and a guarantee that Aigentine neutral rights would thenceforth be respected. But upon delivery of the German reply, revealed July 6, the Argentine government accepted the excuse of mistaken identity, agreed to waive the salute to the flag, and undertook to provide Germany with information on Argentine ship sailings so as to prevent further incidents. When Germany announced a blockade of eastern North America, Argentine ships were rerouted to gulf and Pacific coast ports. These developments brought vigorous criticism in the chamber of deputies, where the party division was close, and before adjourning on Sept. 30, the chamber by a narrow margin voted a resolution favouring a severance of diplomatic relations with axis powers. This action was in line with the position taken at the third foreign ministers' conference at Rio de Janeiro in Jan. 1942, but in view of the Conservative majority in the senate it amounted only to a gesture.

The Castillo administration in the meantime took various steps toward closer co-operation with the other American republics and toward improvement of its own national security. The government in June issued various decrees to enforce economic and financial control measures recommended by the Rio conference. When Brazil declared war on Germany on Aug. 22, 1942, Argentina proclaimed the former a nonbelligerent and declared it would grant all facilities necessary for the defense of Brazilian interests. Closer relations with other Latin American countries were encouraged throughout 1942. Argentine action against axis agents and in support of hemisphere defense was accelerated in Oct. 1942 by the important Boston speech of Undersecretary of State Sumner Welles in which he asserted that Argentine and Chile, the only two American republics which had not yet severed relations with the axis powers, were centres of intrigue and espionage against the United Nations. The

Argentine foreign office protested on the ground that that country should first have been shown the evidence supporting his charges; when such evidence was presented the government undertook an immediate investigation. As a result, 38 persons were arrested on charges of espionage, and 6 of them were remanded for jail terms. When the Anglo-U.S. invasion of North Africa occurred in November, Foreign Minister Enrique Ruiz Guiñazú cabled a statement of Argentine "solidarity" with the U.S. to Secretary of State Cordell Hull. Castillo, on his return to Buenos Aires from a trip to the Bolivian border in Sept. 1942, announced "enormous popular enthusiasm" for his policy of neutrality. Ex-Pres. Justo emerged at about the same time as a potential opponent of the Castillo regime, ostensibly because of differing views on foreign policy. He made a dramatic flight to Brazil to place himself at that country's service in its war against Germany. Castillo on Oct. 5 intervened in Corrientes province and, on grounds of maladministration, removed the pro-Justo government in office there. Minister of War Juan N. Tonazzi, reputedly sympathetic with Justo, soon afterward resigned his post, thereby apparently confirming persistent rumours of an imminent cabinet shakeup.

In domestic politics, the confused situation was somewhat clarified by the ultimate resignation of Pres. Ortiz on June 27, 1942. He had by that time become totally blind; his death followed about three weeks later. Conservative party control, and with it support for Castillo's policies, was restored in the chamber of deputies by congressional elections on March 1, although the Radicals maintained a slim margin of potential influence by being able to combine with Socialist deputies; the senate remained strongly Conservative. The increasingly serious impact of the war on Argentine economy in 1942 forced the adoption of measures designed to conserve domestic supplies of essential materials, including the rationing of automobiles, rubber goods, newsprint and fuels. Continued inflation also was of concern to the government. The year 1942 saw some improvement in transportation facilities, especially in the large expansion of air services provided by Pan American Airways and in the continuation of an Argentine rail link being pushed toward the Bolivian oil fields centring around Santa Cruz.

Argentina still refused to break diplomatic relations with the axis powers during 1943. This policy was maintained despite powerful pressure from the United Nations and in spite of the fact that a Chilean severance of relations on Jan. 20,1943, left Argentina as the only American nation not having so acted. Rumours in May and June indicated that a break might be impending, but control of foreign affairs, both before and after the revolution of June 3-4 (see below) remained in the hands of persons determined to pursue an isolationist policy. The investigation of espionage activities in Argentina, mentioned above, tended to centre around the German naval and air attaché, Capt. Dietrich Niebuhr. When he claimed diplomatic immunity the Argentine government on Jan. 18, 1943, requested his recall. A sharp exchange of notes between Great Britain and Argentina took place at about the same time because of British criticism of Argentine isolation. U.S. Vice-President Henry A. Wallace pointedly ignored Argentina on a semi-official "good will" trip through South America in the early part of 1943. Argentina was also snubbed in failing to be invited to the United Nations food conference held in the U.S. in May

The state of siege which had been proclaimed soon after the attack on Pearl Harbor had been indefinitely

extended on Dec. 14, 1942, and under it the government retained and exercised emergency powers in 1943. The presidential election scheduled for 1944 focused attention increasingly upon domestic politics even to the partial exclusion of the war. Ex-Pres. Justo had emerged by the end of 1942 as the chief opponent of administration policies, but his sudden death on Jan. 10, 1943, removed him as a political factor. Pres. Castillo in late May and early June came out openly in favour of Robustiano Patrón Costas, wealthy and conservative political leader, as his successor a year later. The plans and policies of the administration were apparently aimed particularly at gaining the support of moderates, and it was anticipated that the administration coalition of the National Democratic and Antipersonalista Radical parties would win the elections, whether honest or not. Argentine liberal parties, on the other hand, found difficulty in settling former rivalries so that they could organize a united front for an effective opposition campaign.

The "G.O.U." Coup.—The whole political pattern of mid-1943 was rudely upset on June 3-4 by an almost bloodless revolution of a clique of army officers headed by Gen. Arturo Rawson and Gen. Pedro Pablo Ramírez. The group deposed Pres. Castillo and set up a provisional government with Rawson in the presidency; he gave way after two days to Ramírez, and on June 18 the new regime was declared to be permanent. Observers, both in and out of Argentina at first hoped, and many assumed, that the new administration would be less conservative than the Castillo government and would quickly break with Germany and Japan. Such expectations were quickly dissipated by cabinet and other appointments that soon made it apparent that the new government was pursuing a vigorously nationalistic policy and was even more conservative than the one it had displaced. Many of its leaders, including Ramírez, had been associated with Argentine fascist groups. It soon appeared that the inspiration of the new regime was the army "colonels' clique" popularly known as the G.O.U. (Grupo de Oficiales Unidos; the initials were sometimes explained as standing for the slogan Gobierno, Orden, Unidad) and that the dominant figure behind the scenes was the able army officer Col. Juan D. Perón.

An early wave of criticism of the new government's policies was followed promptly by a rigorous proscription of pro-Allied and pro-democratic newspapers; more than 70 papers were suspended in September alone for varying periods, and some editors were jailed. When Bruno Genta, a federally-appointed interventor, removed many liberal faculty members from the University of the Litoral, a serious student protest riot resulted. Additional disturbances occurred in the last two months of 1943 among students in other national universities. The government suspended many pro-Allied organizations on the charge that they were communistic; chief of these was the Junta Feminina de la Victoria, a women's group including many of the most prominent women of the country and engaged in raising supplies and contributions for the Allied cause. Similar attempts against labour unions resulted in extensive strikes, and the government was forced in some cases to modify its position. One of the most serious strikes started in September among employees in meatpacking plants in Avellaneda, a Buenos Aires suburb; before its end on Oct. 4, the strike resulted in the death or injury of several persons during demonstrations. A general strike began late in November at Mar del Plata over the attempted imposition of a heavier tax on bicycles; this strike continued until Dec. 15 and brought not only

the arrest of various labour leaders but also a material reduction in the proposed tax. The government on Dec. 31, 1943, decreed the dissolution of all political parties as of that date. The purposefulness in the new government's program was pointed up by the revelation, late in 1943, of a manifesto secretly issued to Argentine arms officers on March 5, 1943, three months before the revolution, in which German techniques and objectives were lauded and the same sort of totalitarian program advocated for Argentina under the aegis of the army.

Other internal policies of the Ramírez government included a number of measures designed to secure popular support: abolition of the official wine and grain boards, elimination of the much disliked Buenos Aires transportation monopoly, cuts in utilities rates, adoption of a national rental reduction program, a reduction in the civil service for reasons of economy, an increase in pay for government employees, an increase in the minimum wage for farm labour and a 20,000,000-peso increase in farm loans. The new regime took vigorous and nationalistic economic action. Most important was the announcement in mid-September of the decision to repatriate £33,000,000 of Argentina's £46,000,000 of London-held bonds. The British-owned water system serving parts of Buenos Aires province was purchased by the government in May 1913 for 10,000,000 pesos. The year showed a considerable favourable balance of trade, and foodstuffs were generally plentiful, although shortages in fuel oils and rubber were serious; linseed oil and corn were used in large quantities as a fuel substitute.

The high point of development in foreign affairs after the June revolution resulted from the effort made in early September by Foreign Minister Admiral Segundo Storni to obtain lend-lease aid from the U.S. with which to improve and enlarge Argentina's military establishment, especially in view of the large amounts of lend-lease aid currently being obtained by Brazil, Argentina's only South American rival. Secretary Hull's refusal of the request was accompanied by a severe castigation of Argentina's alleged failure to co-operate with the other American republics in maintaining hemisphere security. A political sensation resulted in Argentina and Storni's resignation followed, presumably because of Argentine loss of diplomatic face, but no general change in policy resulted and, indeed, some observers felt that Hull's note tended to rally Argentine opinion to greater support of the government. Gen. Rawson in the same month delayed his departure for Rio de Janeiro to assume his new ambassadorship to Brazil, and instead toured the country making addresses in favour of a break with the axis powers. The government finally had to order him to leave for his post, refusing to accept his proffered resignation. Argentina on Aug. 23 signed a contract with Great Britain, the latter acting on behalf of the United Nations, by which the entire Argentine exportable meat surplus for a two-year period was pledged to Great Britain and other United Nations. The same two countries in November entered into a pricefixing agreement on quebracho.

Argentina also negotiated commercial treaties with Chile and Ecuador during 1943. The 1943 treasury deficit of approximately 734,810,000 pesos was the largest in Argentine history to that date.

The Ramírez government continued on its nationalistic course. On Jan. 5, 1944, it decreed stringent new press regulations, including a prohibition on publication of "anything contrary to the general interest of the nation."

The independent course of action was reflected by Argentine recognition of the revolutionary Bolivian junta, put in power by the coup of Dec. 20, 1943, even though other American foreign offices delayed for some months to consult about the Bolivian situation. The Argentine foreign ministry announced Jan. 21, 1944, the arrest several months earlier, by British officials at Trinidad, of Argentine Consul Osmar Helimuth, en route to Barcelona, Spain, on charges of espionage. Ensuing revelations of axis activity in Argentina, plus some indirect pressure by the U.S. state department, culminated on Jan. 26 in an Argentine break with Germany and Japan. Those powers' ambassadors were given their passports and later steps were taken to complete the rupture. Pres. Roosevelt and Secretary of State Hull hailed the break, though in somewhat cautious terms, pending later indications of genuine Argentine acceptance of a policy of continental solidarity. Severance of diplomatic relations with axis satellites followed on Feb. 4.

Perón Emerges.-These important developments were soon followed by even more dramatic events in domestic politics. A swiftly executed coup by an inner clique among the G.O.U. on Feb. 24, 1944, ousted Pres. Ramírez and put in his place Vice-President Gen. Edelmiro Farrell. The action was allegedly taken because the officers, supposedly extremely nationalistic and noninterventionist, feared the government planned a declaration of war against the axis. Many changes in cabinet and other high positions followed. Two central figures in the struggle for power emerged: Col. Perón, undersecretary of war, who became minister of war on May 4, and Gen. Luis C. Perlinger, minister of government. The contest resulted successfully for Perón when he was named vice-president on July 8, 1944; Perlinger resigned his ministry on July 5. Perón also headed the labour secretariat.

An immediately pressing problem was that of recognition by other governments. Chile, Bolivia and Paraguay all asserted to be under more or less diplomatic and economic pressure from Argentina, extended recognition in March; the other American republics, all of which had promptly recognized the change of regime in June 1943, postponed action and conferred at length over the situation. The administration in the following months took many strongly nationalistic steps, such as the strict regulation of the press and the temporary suspension of many papers (including the outspokenly democratic La Prensa), reparation of portions of the foreign debt, expropriation of foreign-owned public utilities, temporary detention of many former officials (including Gen. Rawson), stricter regulation of foreign enterprises and economic activities, and a heavy rearmament program. The last-mentioned had led by the end of 1944 to the organization and equipment of two armies of six divisions each, three army air force squadrons with four air bases, and four military institutes. The navy by that time included two battleships, three cruisers, 15 destroyers, three submarines, four coast defense ships, four transports, three surveying vessels, two river monitors, two oilers and five tugs; the navy also possessed two bases, three training schools and an air force of three squadrons. The government on May 18, 1944, decreed that all boys of high-school age must serve in the army for 12 months instead of the three previously required, and on Nov. 17 it declared all citizens between the ages of 12 and 50 subject to military training. In the face of a storm of protest against that tender lower age limit the government later asserted that the youth of both sexes

below 20 years of age would receive only athletic training.

Because of the tightening diplomatic situation, most of the representatives of the other American republics, including U.S. Ambassador Norman Armour, were called home late in June and early in July; Argentina retaliated by recalling some of its foreign representatives. A note circulated by the U.S. among the other American republics on July 20 made outspoken charges against the Argentine government, which Foreign Minister Gen. Orlando Peluffo promptly denied. Relations between Argentina and the U.S. continued to deteriorate for some time thereafter, with Secretary Hull attempting to point up a distinction between the Argentine people and that country's government.

Enormous Buenos Aires demonstrations on Aug. 23-24, 1944, celebrating the liberation of Paris (not actually liberated until the 25th) were interpreted as a veiled protest against government policies, and many arrests followed. The government on Sept. 9 announced the withdrawal of its representative on the Committee for the Political Defense of the Hemisphere, at Montevideo, Uruguay, because of that body's critical attitude toward the Argentine regime. Pres. Roosevelt on Sept. 29 strongly denounced the Argentine policy. The foreign ministry precipitated a diplomatic sensation on Oct. 26 by requesting that a fourth foreign ministers' conference be held to consider the inter-American official attitude toward Argentina. Prolonged diplomatic discussions followed, but nothing tangible was announced until the Pan American Union's statement on Jan. 7, 1945, that the request would be deferred indefinitely because of a previous decision to hold an early special conference (which had been hastily arranged in the meantime) on war and postwar problems.

The Pan American Union's announcement of plans for the Inter-American Conference on Problems of War and Peace, to which Argentina was not invited, caused that state to withdraw its representative from the Pan American Union governing board in Jan. 1945; he did not resume his seat until March 12. The special conference, held at Mexico City, Feb. 21-March 8, 1945, consciously subordinated the Argentine question to more general problems. The conference late in its sessions took the position that if Argentina adhered to the steps taken at Mexico City (especially the Act of Chapultepec), declared war on the axis, signed the United Nations pact, and took other measures to demonstrate hemispheric accord, it would be readmitted to the community of American states, presumably prior to the meeting of the United Nations Conference on International Organization at San Francisco in April 1945. Pres. Farrell announced on March 27 that war had been declared against the axis powers in order to "identify the policy of the nation with that of the other American republics." Argentina then asked to sign the Act of Chapultepec and its representative did so at Mexico City on April 4. The government in early April took steps to round up suspected axis agents, close pro-nazi newspapers, and confiscate enemy alien property; U.S. officials later expressed doubt as to the genuineness of some of these measures. The U.S. state department announced on April 9 that all American republics had agreed to resume "normal diplomatic relations" with Argentina. Pres. Harry S. Truman on April 9 nominated Spruille Braden as ambassador to Argentina; Braden presented his credentials at Buenos Aires May 21. After sharp debate in the opening days of the San Francisco conference, with the opposition led by the U.S.S.R., Argentina was admitted to membership. Argentina ratified the

Domestic politics reflected many changes in 1945. Early months were characterized by general unrest and increased

democratic opposition to the regime. The government

stepped up its political arrests and exiling of opponents. Opposition leaders, concentrated principally in Montevideo, found it difficult to form a united front against the Farrell-Perón government. The administration on May 31 published a new and subsequently controversial statute for political parties with various novel features, including compulsory voting and a ban on "exotic ideologies." Correspondent Arnaldo Cortesi published in the New York Times a sensational dispatch charging dictatorial methods and corruption on the government's part; repercussions were heard for several weeks. Buenos Aires newspapers on June 16 published a manifesto by 321 industrial and commercial organizations attacking governmental policies. Despite continuing disturbances, the government on Aug. 6 lifted the state of siege in effect after Dec. 16, 1941. Ambassador Braden, who, during his tenure in Buenos Aires, made several critical statements about the government, was promoted to the position of assistant secretary of state in charge of American republic affairs on Aug. 25, implying a more severe U.S. policy toward Argentina; he left Buenos Aires on Sept. 23.

Gen. Arturo Rawson was arrested on Sept. 25, 1945, for alleged leadership of an attempted revolution. The government on Sept. 26 restored the state of siege. Civilian leaders expressed little faith in Pres. Farrell's earlier announcement that elections would be held before the end of 1945. A coup led by Gen. Eduardo J. Avalos and Adm. Héctor Vernengo Lima ousted Vice-Pres. Perón from his various posts on Oct. 9 and forced considerable governmental reorganization, though Pres. Farrell remained in office. But

Perón, by a countercoup on Oct. 17, succeeded in return-

Argentina: Statistical Data

ing to power (though he did not resume his offices) with the mass support of certain labour elements which had been backing him for the presidency. The government on Nov. 14 set Feb. 24, 1946, as the date for elections, and in the meantime Perón made his long-delayed formal announcement of candidacy. The government on Dec. 20, supposedly to aid Perón's candidacy, which it supported, decreed a general 10% to 25% wage increase and payment of a Christmas bonus of one month's salary; this encountered an adverse judicial decision on March 23, 1946. On Dec. 30, 1945, the Democratic Union, a coalition composed of the Radical party and other opposition groups, nominated José P. Tamborini and Enrique P. Mosca as its presidential and vice-presidential candidates respectively.

The government in July 1945 announced plans for a large housing program, involving the expenditure of 200,000,000 pesos annually for 20 years, to supplement its slum-clearance projects. The U.S. and Argentina concluded an agreement on May 10, 1945, for large-scale purchase by the U.S. of linseed and vegetable oils in return for the supply of large quantities of fuel oils to supplement inadequate Argentine fuel resources. Argentina on Aug. 4 announced consummation of a trade pact with Sweden. Late in 1945 it gave notice of intention to end the 1936 trade agreement with Great Britain, effective Feb. 21, 1946.

The Labour party, a Perón creation, and a dissident pro-Perón wing of the Radical party in Jan. 1946 nominated Dr. Hórtensio J. Quijano as Perón's running-mate. Campaigning in January and until the elections of Feb. 24 was frantic, with the opposition charging that the government was throwing every possible obstacle in the way of its candidate, Tamborini. Perón on Jan. 30 charged that the U.S. embassy was involved in smuggling arms into Argentina (the foreign office later repudiated the charge), but on Feb. 9 he made a bid for closer relations with the U.S. The U.S. state department on Feb. 12 published a startling memorandum on the Argentine situation in which it charged negotiations for nazi military assistance to Argentina, efforts by the latter government to subvert the governments of neighbouring countries, Argentine-nazi political and social collaboration, and the existence of a strongly fascistic government in Argentina. This "Blue Book" was a diplomatic bombshell and caused strong attacks by Perón on Spruille Braden as well as formal repudiations by the Argentine government.

Perón President.-If the "Blue Book" was designed to bring about Perón's defeat on Feb. 24, 1946, it failed badly. The election was peacefully held, the votes apparently were honestly counted, and, to the surprise of many observers, Perón won an overwhelming triumph, the final electoral vote being announced as 304 for Perón to 72 for Tamborini; the popular votes were respectively 1,474,-447 and 1,207,359. Composition of the new congress was 109 pro-Perón deputies against 49, and 26 favourable senators against 4 anti-Perón senators. Some observers subsequently explained the victory on the basis of Perón's successful cultivation of the labouring classes with many promises of betterment of their condition. The Democratic Union was formally dissolved on April 16; Perón on May 23 announced the merger of all parties which had supported him into one new one, the National Revolutionary party.

The U.S. on March 21, 1946, notified all other American governments except Argentina that it would not

sign a proposed permanent hemispheric peace and security pact, anticipated by the Act of Chapultepec, if the Perón government were a signatory; this position was in effect reversed in early April, however. At about the same time George Messersmith, U.S. ambassador to Mexico, who had taken a prominent role in getting Argentina admitted to the San Francisco conference, was named U.S. ambassador to Argentina; he and Sir. R. W. A. Leeper, the new British ambassador, both arrived in Buenos Aires on May 22. Various steps toward a rapprochement occurred later in the year, notably attendance by Pres. Perón at a U.S. embassy dinner given Aug. 9, 1946, for Oscar Ivanissevich, newly named Argentine ambassador to the U.S.

The chamber of deputies met April 29 for the first time after 1943, with Perón forces in full control. The state of siege was again lifted on May 24. Various nationalistic steps occurred in the early months of 1946: a decree of March 25 nationalized the Central Bank of the Argentine Republic; a new tax law in May heavily penalized absentee land-owning; the government on May 30 put stock exchanges and export and insurance businesses under national control; the Perón-controlled paper El Laborista predicted that various foreign-owned oil concessions would be expropriated. On May 31, 1946, Perón was reinstated on the army active list and promoted to be a brigadier general, effective Oct. 17, 1945. Inauguration of Perón and Quijano took place with elaborate ceremonies on June 4, third anniversary of the coup that had brought the military clique to power. Perón declared on Aug. 1, 1946, that in the event of another world war Argentina would fight on the side of the U.S. The government on July 16 announced a decision to retire all outstanding foreign dollar and Swiss-franc debt, estimated to total more than \$125,000,000.

Arizona

The "Grand Canyon state" lies in the southwestern part of the United States. It borders Mexico on the south; the Colorado river forms most of the western boundary. Arizona and New Mexico are the youngest states of the United States, both being admitted in 1912. Area 113,909 sq.mi. including 329 sq.mi. of water. Population (1940) 499,261, including 65.2% classified as rural and 34.8% as urban. Native and foreign-born whites (including Mexicans) numbered 389,955 and 36,837 respectively; Negroes 14,993; other races (mostly Indian) 57,476. Estimated population in 1944, 638,412. The capital is Phoenix with a population (1940) of 65,411. Chief cities are: Tucson (36,818); Douglas (8,623); Mesa (7,224); Globe (6,141); Prescott (6,018); Bisbee (5,853); Yuma (5,325); and Flagstaff (5,080).

The state officials in 1937 were: chief justice, A. G. McAlister; governor, R. C. Stanford; secretary of state,

J. H. Kerby; attorney general, J. Conway; treasurer, H. M. Moore; auditor, Ana Frohmiller; superintendent of public instruction, H. E. Hendrix. The governor and the entire legislature, with one exception, were Democratic. The governor's chief plank was his proposal to increase taxes on mines and railroads and to reduce the sales tax by a corresponding amount, with foodstuffs, fuel and cheaper clothing to be eliminated entirely from the sales tax. Owing to conflicting interests within the legislature and also to those between the legislature and the executive, three special sessions were called, the last adjourning Aug. 4, 1937. The governor's sole victory in the special sessions was the provision that 60% of the sales tax be returned to the counties to relieve them of depression-caused debts.

The November election of 1938 for the state returned the incumbents with three exceptions: Robert T. Jones, governor; H. M. Moore, secretary of state; and William Peterson, treasurer. At the November election of 1940 Sidney P. Osborn was elected governor; Joe Hunt, treasurer; and Alfred C. Lockwood became chief justice. In the presidential poll, Roosevelt received 95,267 votes; Willkie, 54,030. Ernest W. McFarland was elected U.S. senator, having defeated Senator Henry F. Ashurst in the September primary.

Governor Osborn in 1941 proposed the consolidation of bureaus and offices, a new board of control for the state hospital, and an increase of old-age pensions from \$30 to \$40 per month. The last two measures were formulated into law.

In the November elections of 1942, all state officials were re-elected with the exception of Joe Hunt, who was elected state tax commissioner; J. D. Brush was elected treasurer of the state. Secretary of State H. M. Moore died during the year and Dan E. Garvey was appointed by the governor as his successor. A special war session of the 15th state legislature passed several measures, including a bill providing for a civilian defense board and a defense council. Archibald G. McAlister, chief justice, was the only new state official in 1943. The legislature passed 96 acts during 1943, including an act authorizing the signing of a contract between the United States and Arizona providing for "delivery for use in this state of all such waters of the Colorado river as are available for use in this state."

The state officials in 1944 were: chief justice, Archibald G. McAlister; governor, Sidney P. Osborn (re-elected 1944); secretary of state, Dan E. Garvey (re-elected 1944); treasurers, James D. Brush and by appointment Alva Weaver (William T. Brooks elected 1944); attorney general, Joe Conway (John L. Sullivan elected 1944); superintendent of public instruction, E. D. Ring (re-elected 1944). The vote in the presidential election (1944) was: Roosevelt 80,926, Dewey 56,287. The legislature ratified the Santa Fe compact and the contract calling for delivery to Arizona of 2,800,000 ac.ft. of water from Lake Mead, gave the right of voting to soldiers and established a change of time. Chief Justices Henry D. Ross (died Feb. 9, 1945) and Rawghlie C. Stanford were new state officials in 1945. The legislature during 1945 passed a measure providing for a single board of regents for the University of Arizona, Tucson, Ariz., and the two state teachers' colleges, made provision for a survey of the use and supply of underground water for irrigation and for evaluating gas and electric plants as a basis for rate-making.

Governor Osborn and all state officials were re-elected on Nov. 5, 1946, except the treasurer and the superintendent of public instruction; Mit Simms and Nolan D. Pulliam were elected, respectively, to the latter offices.

Arkansas

Located in south-central United States, Arkansas was the 25th state admitted to the union (1836). Its older popular name was "Bear State," the newer (by act of the legislature), "Wonder State." Area, 53,102 sq.mi., including 377 sq.mi. of water. Population (1940) 1,949,387, of which 22.2% was urban. The white population was 1,466,084; Negro, 482,578; other, 725; foreign born, 7,692. Estimated population (1944), 1,776,446. The capital is Little Rock (pop. 1940, 88,039). Other cities: Fort Smith (36,584); Hot Springs (21,370); Pine Bluff (21,290); North Little Rock (21,137); El Dorado (15,858), Texarkana (11,821).

State officials in 1937 were: governor, Carl E. Bailey; lieutenant governor, Bob Bailey; secretary of state, C. G. Hall; attorney general, Jack Holt; comptroller, J. O. Goff. Important bills passed by the 1937 legislature included those creating a department of public welfare, establishing a merit system for office holders, refunding the debt, prohibiting competition of prison labour with free labour, creating a commission for interstate co-operation, changing the sales tax, providing for unemployment compensation, providing for soil conservation, revising the corrupt practices act, enacting a retirement act for teachers, providing for housing authorities in certain cities and for a state police. An amendment to the constitution exempted home-

steads from state taxes, and another act gave power of reapportionment to a commission consisting of the governor, the secretary of state and the attorney general.

Constitutional amendments adopted in 1938 included those allowing the legislature to pass a workmen's compensation act, giving the supreme court authority to regulate the legal profession, exempting new factories and extensions of old ones from state taxation for ten years, regulating appointments to fill vacancies and providing for nomination by majority vote only. An amendment to substitute registration for the payment of a poll tax as a prerequisite for voting was defeated by a large majority.

In the 1940 presidential election in the state Roosevelt received 158,622 votes, Willkie, 42,224. State officials elected for a two-year term were: Homer M. Adkins, governor; Bob Bailey, lieutenant governor; C. G. Hall, secretary of state; Jack Holt, attorney general; Otis Page, land commissioner; Earl Page, treasurer; J. Oscar Humphrey, auditor; J. S. Holt, associate justice of the supreme court. The Communist party was ruled off the ballot on the ground that it did not "subscribe to the principles of Americanism."

Legislative acts of importance in 1941 were: the refunding of the highway debt with the RFC at a lower rate of interest; a measure allowing cities of the first class to levy taxes to pay salaries and pensions of firemen and policemen; establishment of civil service in cities with a population of 20,000 or more; authorizing the governor to join interstate compacts for the conservation of oil and gas; forbidding political parties to name candidates except through primaries or conventions.

In the November elections of 1942 the following new officers were elected: J. L. Shaver, lieutenant governor; Guy E. Williams, attorney general; Claude E. Rankin, land commissioner. Three new members were elected to the supreme court, Ben E. Carter, Edward F. McFaddin, R. W. Robbins. Two new members were sent to the house of representatives, J. W. Fulbright and Brooks Hays. John L. McClellan was sent to the senate. Although about 300,000 had paid the poll tax, fewer than 100,000 went to the polls. Four amendments to the constitution, one referred act and one initiated act were submitted to the electors. Two amendments were adopted, one to allow counties to support hospitals by taxation and the other to "freeze" boards of state institutions and to "stagger" terms so that it would be impossible for the governor to get control. The initiated act, reducing the number of signatures required to submit a local option measure, was adopted. The referred "lawyers bill", to require the employment of lawyers in certain cases, was defeated.

The aluminum plant situated near Lake Catherine went into operation in 1942, making aluminum out of ore mined a few miles away. Arkansas could now produce 180,000,000 lb. a year. Sour gas from south Arkansas was being used for fuel in the aluminum plant. Arkansas secured several war industries, army camps and flying fields at a cost, according to Governor Adkins, of \$350,000,000. Two colonies of Japanese who had been evacuated from the west coast, were established in the state. (D. Y. T.; X.)

The general assembly met in Jan. 1943 for its 54th regular session. Except for passage of the Abington bill, which outlawed the forcing of strikes by violence, controversial measures were significantly avoided.

In the biennial state election of Nov. 7, 1944, Ben T. Laney was elected governor; C. G. Hall, secretary of state; J. O. Humphrey, auditor; J. L. Shaver, lieutenant governor; J. V. Clayton, treasurer; Guy E. Williams, attorney general; C. A. Rankin, land commissioner. Amendments

guaranteeing the right of the individual to work without union affiliation, creating a game and fish commission, and allowing servicemen to vote without payment of poll tax, were adopted. Acts to repeal the law legalizing horse and dog racing and to establish a system of state hospitals, were defeated. In the presidential election, Arkansas cast a total vote of 212,954, of which 148,965 went to the Democratic party, 63,551 to the Republican and 438 to other parties.

The chief accomplishments of the Laney administration during 1945 were a reduction in state employees and total expenses; consolidation of all natural resource agencies

expenses; consolidation of all natural resource agencies

into one, with resulting economy and efficiency; improved finances for public schools; and a new method of allocating state revenues to vital services which largely eliminated earmarking of special tax levies and assured continuous operation of necessary service during periods of reduced income.

All the principal state officers were re-elected in Nov. 1946, for two-year terms, except the lieutenant governor, who was not a candidate. Nathan Gordon became lieu-

tenant governor for 1947 and 1948.

Arnim, Dietloff Juergen von

Arnim (1891?-), German army officer, was born of a wealthy and noble family. Little information on his early military career became available; it was known, however, that he worked with Erwin Rommel prior to World War II on plans for building up the wehrmacht's panzer forces. Although an expert in mechanized warfare, he served in the Polish campaign (1939) as commander of an infantry division. After Rommel's recall to Germany in March 1943, for "reasons of health," Arnim was over-all commander of German forces in Tunisia. Under his direction, the Afrika Korps put up a strong defense of the so-called "coffin corner" of Tunisia, but Allied superiority in arms and manpower soon wore down the resistance of the German forces. After Allied armies took Bizerte and Tunis on May 7, 1943, Arnim's units were driven back to the Cape Bon peninsula. Taken prisoner on May 12, 1943, he requested surrender terms from Gen. K. A. N. Anderson, commander of the British 1st army.

Upon learning that he would be given only "unconditional surrender," Arnim angrily refused to sign. However, his armies were already surrendering in droves. In a final message to Hitler, Arnim wrote: "I report that the order to defend Tunisia to the last cartridge has been carried out." Von Arnim was despatched to England for internment and was subsequently shifted to the United States.

Arnold, Henry H.

Arnold (1886—), U.S. army officer, was born June 25, 1886, in Gladwyne, Pa. After graduating from the U.S. military academy at West Point in 1907, he served two years in the Philippines. During World War I, he was assigned to the signal corps aviation division and later became assistant director of military aeronautics. Gen. Arnold, who was named assistant chief of the air corps in 1936, became a major general and chief of the air corps two years later. In 1940 he was appointed deputy chief of staff for air. In the spring of 1941, Gen. Arnold went to England to exchange technical knowledge with British air experts and in December of that year Pres. Roosevelt named him for temporary promotion to the rank of lieutenant general. In March 1942 Arnold was made com-

mander of the U.S. army air forces, which were given equality with the ground forces. He was promoted to a full general in 1943 and in 1944 was raised to the highest military rank—general of the army. On Jan. 24, 1946, Gen. Arnold was succeeded as head of the army air force by Gen. Carl A. Spaatz.

Arnold, Thurman Wesley

Arnold (1891—), U.S. attorney and government official, was born June 2, 1891, in Laramie, Wyo. After completing his law studies at Harvard (1914), he practised law in Chicago and later in Laramie. During World War I, he served in France as an officer in the field artillery. He was dean of the West Virginia university college of law from 1927 to 1930, and professor of law at Yale university in 1931. Four years later he was appointed trial examiner for the Securities and Exchange commission.

Arnold was the target of anti-New Deal attacks after publication of his work, The Folklore of Capitalism (1937), in which he referred to U.S. law and classical economics as a compound of myth and fiction. Shortly thereafter, he was appointed assistant attorney general by Pres. Roosevelt (March 1938). In this office, Arnold conducted a concerted anti-trust drive; he filed suits against the major motion picture companies (1938), employers and unions in the building industry (1940), and the Associated Press (1942). On July 5, 1945, Pres. Truman announced that he had regretfully accepted his resignation.

Arsenic

The output of white arsenic in the major producing countries during 1937-45 is shown in Table I.

Table I .- World Production of Arsenic

	(The	usands	of shor	t tons)				
	1937	1939	1940	1941	1942	1943	1944	1945
Australia Belgium (exp.)	2.30 3.35	1.59 3.67	3.73	3.78	3.05	2,56	2,58	ş
Brazil	0.79	0.78	1.19	1.29	0.99	0.93	ş	Š.
Canada	0.69 7.17	0.87 ?	1.05	1 <i>.77</i> 6.77	3.92 2.49	1.58 4.12	1.31	1.02

Mexico	11.86	7.79	10.22	14.16	20.41	22.39	16.87	16.55
United States	16.81		24.98	32.48	28.68	31.20	36.09	24.35
Total	61. <i>7</i>	69.5	79.2	ş	ş	ş	ş	ş

Although world data were not yet sufficiently complete at the end of 1946 to estimate the total output from 1940, the figures available indicated a maximum of the order of 90,000–100,000 tons in 1943, with subsequent decline. In addition to the countries listed in Table I, Sweden was an important producer of crude arsenic, as a byproduct from arsenical gold ores, only small amounts of which were refined for sale, as the supply greatly exceeded demand. After World War II the Swedish stocks of crude, estimated to be of the order of 400,000 tons, could be distributed to meet European demands, lightening the demand on Mexico and the United States.

Table II.—Data of the Arsenic Industry in the United States
(Thousands of short tons)

						Produ	etion		lm-	Ex-	Con-	
						Crude	Refined	Total	Sales	ports	ports	sumption
1937	٠					9.9	6.9	16.8	17.6	19.3	2.2	34.7
1938						12.6	4.1	16.7	13.2	14.2	2.3	25.1
1939		٠				1 <i>7</i> .5	4.8	22.3	22.4	14.7	3.2	33.9
1940						18.2	6.7	25.0	23.3	9.9	1.6	31.6
1941						26.8	5.6	32.5	34.8	10.3	2.1	40.4
1942				٠		25.7	3.0	28.7	31.0	16.4	0.3	41.5

1944					٠	31.2	4.9	36.1	34.5	10.0	2.4	43.5
1945						21.4	3.0	24.3	24.8	13.1	0.0	30

Although U.S. production increased materially during the war years, and consumption increased more than production, the advances in consumption were largely in es-

tablished uses, rather than war uses, especially insecticides and weed killer. There was some war use of arsenic, but information was lacking on the amount and the specific uses. Arsenic is a constituent of the war gas lewisite, and apparently much of such war demand as did develop was for this product, none of which was actually used; its manufacture was only a precaution, so as to be prepared if the axis nations instituted the use of gas warfare. Demand for arsenical pharmaceuticals, which nearly trebled between 1939 and 1942, was greatly reduced by the substitution of penicillin for arsenicals in the treatment of venereal diseases, as well as by the demobilization of the armed forces.

While U.S. consumption in 1945 had declined almost a quarter below the high of 1943, it was still 15% higher than in any prewar year.

Arteaga y Betancourt, Manuel

Cardinal Arteaga y Betancourt (1879—), Cuban prelate, was born Dec. 28, 1879, at Camaguey, Cuba. His family emigrated to Venezuela for political reasons, and Arteaga was ordained in Caracas in 1904. After representing the Caracas archdiocese at the International Eucharistic congress in Madrid, Spain, he returned to Cuba in 1911. He was named archbishop of Havana in December 1941, and was consecrated the following February.

Arteaga, who was a member of the Third Order of St. Francis and the Knights of Columbus, served the Havana council as chaplain. Venezuela awarded the archbishop the Simon Bolivar Soles y Rayos decoration while Cuba conferred upon him the Order of Carlos Manuel de Cespedes. During his administration of the See of Havana, he built the Good Shepherd seminary at Arroyo Arenas and a number of churches and chapels. He was nominated to the College of Cardinals on Dec. 23, 1945, and was proclaimed cardinal at the consistory in Rome, Feb. 18, 1946.

Art Exhibitions

During the ten years 1937-46 art exhibitions increased to an enormous extent. Several new museums were completed before World War II curtailed building activities, many new sales galleries opened and throughout the United States exhibition programs were greatly expanded. Rising attendance figures indicated that many more people were going to see exhibitions; public interest in art was aroused and the standard of public taste was raised.

Prewar U.S. Exhibitions.—The year 1937 started out significantly with a comprehensive exhibition of America's most important "old master," John Singleton Copley, at the Metropolitan museum in celebration of the bicentennial of the artist's birth (a date which, however, was subject to dispute). This sounded the note of a decade which was to emphasize American art. Forty-eight paintings afforded a rare opportunity to study all phases of Copley's work and asserted once more the importance of this straightforward, uncompromising New England limner.

With equal thoroughness, the Whitney museum celebrated the centennial of Winslow Homer's birth with a comprehensive showing of 170 paintings and water colours

as well as prints and drawings. Thus the most American painter of the 19th century could be seen in all his force-fulness and vigour.

A unique and fascinating event was arranged at the Albright Art gallery in Buffalo, N.Y., under the title, Master Bronzes. Five thousand years of the bronze caster's art was demonstrated with 173 pieces, every one of which was a perfect specimen of this most exacting craft. China, ancient Greece, Renaissance Italy and contemporary artists were all represented in supreme specimens.

Another unique exhibition, The Dark Ages, was shown at the Worcester museum. With material from the excavations at Antioch, Syria, the art of this little-known period was shown through mosaics, sculpture and various minor arts.

Still more ancient was the collection of 150 prehistoric rock pictures shown at the Museum of Modern Art. By means of the extraordinary copies made by Frobenius, the public was enabled for the first time to become familiar with spirited scenes of hunting and other attivities made thousands of years before the dawn of recorded history.

Of enormous interest was the Museum of Modern Art's comprehensive survey of photography beginning with Daguerre's first successful experiments of 1839. From his name came the daguerreotype which in the 1840s was so popular that it threatened to displace portraiture. David Octavius Hill, Mathew Brady, A. Nadar, Alfred Stieglitz, Charles Sheeler, Man Ray and many other notable photographers were shown to advantage. (See also Photography.)

Nineteenth century France was the subject of three memorable exhibitions: Daumier, the great satirist, at the Philadelphia museum; Renoir, the sensual colourist, at the Metropolitan museum; and the most comprehensive group of Manets ever assembled in the U.S. at the Durand-Ruel galleries.

In 1938 the Museum of Fine Arts in Boston held another large and important Copley exhibition to celebrate the 200th anniversary of the artist's birth. Another bicentennial took place at the Philadelphia museum, where Benjamin West was accorded the first major exhibition in a number of years.

Two memorial exhibitions of unusual interest were held at the Whitney museum, Charles Demuth and William Glackens. Much forgotten material was brought to light in the Whitney's Century of American Landscape Painting, 1800–1900.

Another significant note in the American field was the showing of two brothers, Charles and Maurice Prendergast at the Addison gallery in Andover.

If Buffalo in the previous year had attracted interest to the wide use of bronze, the Metropolitan museum in 1938 emphasized the importance of bronze in one area, namely, China. A princely assemblage of 372 pieces represented a period from the earliest known examples in the Shang dynasty to the Sung dynasty (960–1279 A.D.).

Also at the Metropolitan was another exhibition of metal—a handsome group of rare French domestic silver from the 16th to the 19th century. The palace of the Legion of Honor in San Francisco attracted nation-wide attention with a splendid exhibition of Venetian painting. Chicago's Art institute, also in the Venetian field, assembled a brilliant group of paintings and drawings by Giambattista and Giandomenico Tiepolo. In quite a different vein, Mrs. Josephine Hancock Logan, in opposition to progressive or modern trends in art, organized the Society

for Sanity in Art and put on a reactionary exhibition at the Chicago galleries.

In 1939, the Metropolitan museum assembled an exhibition of Augustan art to celebrate the 2,000th anniversary of the birth of Emperor Augustus.

A joint endeavour of the Worcester and Philadelphia museums was the International Exhibition of Flemish Paintings. Precision of technique and exquisite colour marked this rare school of painting which was so well exemplified. Loans from Europe, such as the Memling "Martyrdom of St. Sebastian" from the Royal museum in Brussels, were significant additions to the group.

A full-length exhibition of 40 years of the work of Pablo Picasso, arranged jointly by the Museum of Modern Art and the Art Institute of Chicago, made an overwhelming impression and won many adherents for modern art.

The Two World's Fairs.—Both 1939 and 1940 were banner years for art in the United States (although war had broken out in Europe), because of the two international fairs—at San Francisco and New York—held in those two years.

San Francisco's fair was the first to open and not only had an excellent survey of contemporary American art but also covered the European field and showed most attractively the primitive arts of the Pacific basin. The great feature, however, was the outstanding loan from the Italian government which included such world-famous masterpieces as Verrocchio's bronze David, Michelangelo's marble relief of the Madonna and St. John, Botticelli's "Birth of Venus," and Raphael's "Madonna of the Chair." This priceless collection was later shown at the Art Institute of Chicago and at the Museum of Modern Art.

New York had murals and sculpture specially done by notable artists in various buildings throughout the fair. In addition there was "American Art Today," a comprehensive cross section of contemporary art, and a special group of old masters which were given added lustre by foreign loans such as Pieter de Hooch's "Linen Cupboard" and Vermeer's "Milkmaid" from the Rijksmuseum in Amsterdam and Chardin's "Grace before Meat" from the Louvre.

During 1940, the two world's fairs continued with emphasis on art. San Francisco staged Art in Action and a fascinated public watched sculptors hew wood and chip stone and painters wield their brushes—including Diego Rivera at work on a large mural. New York arranged an entirely new and even better exhibition of old masters.

Arts of the Middle Ages, 320 top quality paintings, tapestries, manuscripts, ivories and other objects made an outstanding showing at the Boston Museum of Fine Arts.

1940 and After.—A great exhibition of Persian art was arranged in the old Union League club in New York where magnificent carpets, textiles, ceramics and manuscripts were greatly admired despite the disadvantageous setting.

Twenty Centuries of Mexican Art at the Museum of Modern Art afforded the first extensive survey of the art of the U.S. neighbour south of the border. In Pittsburgh, the Carnegie museum put up a well-chosen Survey of American Painting in which the Colonial section showed up to special advantage.

Eastman Johnson (1829–1906), famed for his painting, "My Old Kentucky Home," was revived in an exhibition of 100 paintings and many drawings at the Brooklyn museum.

Though the closing of the two great fairs might seem to have left a gap in available exhibitions, the year 1941 had a full quota of notable showings. The great exhibition of

French paintings of the 19th and 20th centuries, sent by the French government to South America, arrived at the DeYoung museum in San Francisco and went subsequently to the Art Institute of Chicago and the Metropolitan museum, and ultimately found refuge for the duration of World War II at the National gallery in Washington. Ingres' "Turkish Bath" was perhaps the most outstanding picture but every phase of development of French painting was admirably shown.

The Baltimore museum did a fine exhibition of the work of Mary Cassatt, the Pittsburgh girl who became a leading figure among the Impressionist painters of Paris. Another superb Renoir exhibition, this time with 86 pictures, was arranged at Duveen's in New York. The Museum of Modern Art showed the Art of the American Indian in a carefully selected and deftly installed exhibition which proved once and for all the great artistic merit that is inherent in so much material which was formerly dismissed as merely ethnological. Later in 1941 the museum put on a duet, Salvador Dali and Joan Miro, in which Dali showed himself to be a surrealist trickster and Miro was established as an abstract artist of unquestioned distinction.

Coptic art was featured in an exhibition of unusual interest at the Brooklyn museum, and Chicago's Art institute showed a carefully selected group of the paintings and prints of Goya.

The American Scene.—In 1942, there was a definite accent on the U.S., although there were two or three notable exceptions. With the greatest treasures of all of the eastern museums put away as a precaution during the war, the Metropolitan museum's showing of their 16 top Rembrandts came as a breath-taking event. Such favourites as the "Artist's Son," "Titus" and the "Old Woman Cutting Her Nails" seemed to have acquired even finer attributes.

Henri Rousseau, the French "primitive," was given a sympathetic showing at the Art Institute of Chicago. The "Sleeping Gypsy," always a great favourite, was surrounded by jungles, toy landscapes, and woodenlike figures, many seldom seen in exhibitions.

At the Whitney museum the history of American water colour from Copley and Trumbull down to modern times was admirably demonstrated. U.S. artists had brought this medium to a perfection not attained in any other country. Homer and Sargent showed the great possibilities of water colour and were the forerunners of a host of artists in this field.

Two little-known 19th century American painters, John Quidor (1801–1881), and William Sidney Mount (1807–1868), were brought to light in a delightful exhibition at the Brooklyn museum.

The directions that American painting was tending to take were clearly indicated by an exhibition at the Worcester museum where the decade 1930–40 was represented by a carefully selected group of 50 pictures. At the beginning of this period, emphasis was placed on regional painting, the American Scene, but, as the years passed, there was a tendency on the part of artists to be more interested in painting for its own sake without regard for subject matter.

Photography came into prominence when the Museum of Modern Art opened Road to Victory, a superb assembly of 150 photomurals selected by Lieut. Comdr. Edward Steichen, U.S.N.R., and accompanied by a running text specially written by Carl Sandburg. The U.S., its activities and its people were dramatically shown.

Artists for Victory sponsored a huge juried exhibition of painting, sculpture and prints at the Metropolitan museum. Fourteen thousand items were submitted.

At Worcester in 1943, careful research in the early field

of American art resulted in a showing of 55 New England portraits painted prior to the Revolution.

A welcome revival took place at the Brooklyn museum, with a showing of The Eight, the group of New York realists who caused a sensation when they exhibited together in 1908. In the group were Robert Henri, Ernest Lawson, Arthur B. Davies, Everett Shinn, John Sloan, George B. Luks, William Glackens and Maurice Prendergast.

A fine exhibition of the work of Georgia O'Keeffe was a feature in Chicago's Art institute, with the installation effectively carried out by the artist. Sandy Calder, notable as the inventor of "mobiles" and "stabiles" was given a full-length showing at the Museum of Modern Art. His metal constructions, many kept in motion, constituted an entirely new departure in the field of sculpture. The museum also showed two important groups of American painting: Realists and Magic Realists and Romantic Painting in the U.S.

U.S. interest in Latin America, fostered by World War II, was reflected in the Philadelphia museum's showing of Mexican Art Today.

With organizations for world peace coming into prominence in 1944, the Art Institute of Chicago featured Art of the United Nations, composed of one important item from each of 37 nations. This material was most effectively installed in a setting specially designed by Georgy Kepes.

The Cincinnati museum reconstructed, at least in part, the famous Armory show of 1913, which had afforded the U.S. its first view of advance trends in European art. Though the public at large was either terrified or mystified, discerning artists and collectors took note and profited by what was bound to be the trend of the century.

Thomas Eakins, the great 19th century realist, was honoured in his home city, Philadelphia, by a centennial exhibition of major importance. A superbly chosen exhibition of Islamic art was a feature at the Cleveland museum. Exquisite sense of design and colour mark the textiles, ceramics, metalwork and miniatures of the near east, an art less well known than that of China.

Industrial sponsoring of art continued as the Abbott laboratories (one of the first business firms to commission artists) engaged a group of painters, including Joseph Hirsch, Lawrence Beall Smith, Adolf Dehn, to record naval aviation. The results of this project were exhibited throughout the U.S. in one of the most effective war shows.

The Whitney museum, whose galleries had usually been occupied with special exhibitions, arranged a showing of the highlights of their own collection. This served to prove how wisely they had been purchasing in the American field through the years.

In 1945, greater variety appeared in exhibition schedules. French Impressionism came into prominence when the Wildenstein gallery showed the largest group of Monets ever assembled in the United States.

To emphasize the importance of the European artists who had taken refuge in the U.S. during the war, the Whitney museum exhibited the work of those who came after 1938. Max Ernst, Marc Chagall, Fernand Leger, Salvador Dali, Jean Hélion, and Pavel Tchelitchew were among the notables included.

Also at the Whitney was a one-man showing of the New England 18th century portraitist Ralph Earl. His portrait of Roger Sherman was one of the finest characterizations in the annals of early American painting. Organized at the Art Institute of Chicago and later shown at the Whitney was the first large revival of the Hudson River school. Romantic landscape painting in America from 1800 to 1875 made a delightful and highly appreciated assemblage.

Drawings, formerly given scant attention, came into greater prominence as the National Academy of Design started a drawing annual and the Los Angeles museum began a drawing biennial.

Business sponsorship increased. The Encyclopædia Britannica collection was given its first showing at the Art Institute of Chicago before going on a national tour. Upjohn, the pharmaceutical house, assembled an American collection, and Pepsi-Cola for the second time arranged a large juried exhibition with substantial prize money.

More university art departments began assembling collections, as Iowa State followed Arizona and the especially notable precedent set by the University of Nebraska. Annual exhibitions afforded a source from which to make purchases. Four hundred years of landscape painting was a notable feature at the Brooklyn museum.

Postwar Impetus.—During 1946, with the war over and various restrictions removed, exhibitions went on apace. George Bellows was given an impressive revival at the Art Institute of Chicago.

Arts of the South Seas was superbly presented at the Museum of Modern Art and was the most outstanding showing of primitive cultures ever exhibited for their aesthetic qualities. No other art had ever shown greater inventiveness in design and appropriate use of materials.

George Inness, whose popularity had been on the decline, was given a full-scale revival to celebrate the 50th anniversary of the George Walter Vincent Smith Art gallery in Springfield, Mass. With a picture from almost every year of his career, a careful evaluation of his development was possible.

Nostalgia pervaded the atmosphere of New York as Knoedler's, the oldest art firm in town, celebrated its 100th anniversary, while the Metropolitan museum celebrated its 75th birthday with "Taste of the Seventies." In both cases old favourites were brought back as Cabanel, Boucher, Rosa Bonheur and Vibert held sway once more.

Wildenstein showed the most comprehensive group of Gaugins ever assembled. At the Museum of Modern Art, Marc Chagall, the imaginative and colourful Russian-born artist, was given a large retrospective. In Cambridge, the Fogg museum brought out the Pre-Raphaelite pictures from the Winthrop collection and re-evaluated this important English 19th century movement. Watts' "Sir Galahad" and Rossetti's "Blessed Damosel" were among the best remembered in the collection.

Exhibitions to and from England were highlights of the season. Two hundred and thirty American oils and water colours covering the period from the 18th century through the 20th century to date, with emphasis on the contemporary, were sent to London for exhibition at the Tate gallery.

The Art Institute of Chicago was fortunate in being able to negotiate the loan of 63 of the finest Hogarths, Constables and Turners from the king's collection at Windsor, the National gallery, Victoria and Albert museum and the Tate. This collection was the first large group of major pictures ever sent to the U.S. from England. (F. A. Sw.)

Great Britain.—The period 1937–46 was remarkable for a great increase of interest in art, shown most clearly in the attendance at exhibitions of painting. The attendance at the summer exhibitions of the Royal academy alone, which continued throughout World War II, rose from 98,000 in 1939 to 202,000 in 1946; this increase was representative of the larger attendance at galleries of every kind.

In London, the Tate gallery organized an exhibition of the works of John Constable in 1937 on the centenary of his death, and in 1938 the Royal academy held a winter exhibition of 17th century art in Europe of remarkable splendour; among the outstanding works were those of Rembrandt, El Greco, Jan Vermeer, Claude Lorrain and Peter Paul Rubens; this was the last of the series of famous exhibitions at Burlington house, to which masterpieces had been sent from all over the world before World War II. The 1939 winter exhibition was of Scottish art and covered the subject comprehensively from the 17th century to the 20th; a room of portraits by Sir Henry Raeburn was outstanding.

Early in 1940, the National gallery was once more made available for the first of many important exhibitions, "British Painting from Whistler to the Present Day," with 350 canvases. It was followed in November with 100 drawings by Augustus John. A carefully selected exhibition of the work of Walter Sickert in 1941 was complemented by an exhibition of the same artist's pictures at the Leicester galleries. In the same year the Victoria and Albert museum organized an interesting display of the work of Eric Gill, followed by an exhibition to celebrate the tercentenary of the death of Sir Anthony van Dyck. Among the private galleries, Knoedler and Colnaghi held a show of the work of Feliks Topolski. In Jan. 1942 the "Picture of the Month" scheme was started at the National gallery, by now the hub of cultural life in London; it proved immediately popular, averaging more than 20,000 visitors a month with a record attendance of 43,000 to see Sandro Botticelli's "Mars and Venus."

Hertford house was the scene of the first of a number of exhibitions in aid of Allied countries, in this case for Russia, with 900 pictures. Another sign of wartime was the seventh Civil defense artists' show at the Cooling galleries. The National gallery continued to be the scene of important exhibitions: work by Sir William Nicholson and Jack Yeats was shown in January, followed by "Recording Britain," organized by the Pilgrim trust. The principal exhibitions in 1943 were both at the National gallery. The first was a comprehensive one of the work of Wilson Steer and the second was the final show of the "Changing Britain" series organized by the Pilgrim trust.

In London, 1945 was an outstanding year. The National gallery was formally reopened by the king on May 17, with 50 pictures back; the Tate gallery was restricted by bomb damage and continued to be the guest of the National gallery. The Wallace collection reopened in July when Sir Godfrey Kneller's Kit-Kat club portraits were first on view at the National Portrait gallery. At the Leicester galleries the Guedalla collection of the works of Sir Max Beerbohm drew large crowds and the Victoria and Albert museum displayed sculpture removed from Westminster abbey before it was restored. In the autumn began the first of several exhibitions of notable foreign painters: the controversial Pablo Picasso and Henri Matisse exhibition at the Victoria and Albert museum, the Paul Klee exhibition organized by the Tate at the National gallery, and exhibitions of James Ensor, Georges Braque and Georges Rouault followed in 1946. All of these opportunities to see the work of leading modern painters occasioned great interest and stimulating exchanges of views.

In 1946, the collection of English painting belonging to Vincent Massey was on view at the partially repaired Tate gallery before exhibition in Canada. It was followed by a large and important exhibition of U.S. painting from the 18th century at the same gallery where, notable among its re-hung permanent collection, were the Turner and Pre-

Raphaelite rooms. The year ended with the exhibition at Burlington house of the king's pictures, the first time the treasures of the many royal residences had been hung together. The year was also marked by the number and liveliness of the "one man" shows and the scope of the display of old masters at private galleries, among the most important being the Wernher collection at the Wildenstein gallery. Representative exhibitions of the work of living artists from other countries were also organized.

The new interest in pictures was not confined to London; the Cotman centenary exhibition was held at Norwich in 1942, and other important exhibitions during World War II included work by Henry Moore and Graham Sutherland at Temple Newsham, Leeds, and Edward Lear's "Mediterranean Sketches" at Manchester. The *Times* drew attention to the quality of the collection being built up at the Barber Institute of Fine Arts in Birmingham.

The British council organized a considerable number of exhibitions of British art at home and abroad. By the end of World War II, nearly every country had been visited from the U.S.A. to Iceland and from France to Peru.

Continental Europe.—The international exhibition at Paris in 1937 was the occasion of several important exhibitions, including French art in the newly-opened Modern Art gallery and the work of Vincent van Gogh and Catalan art at Maisons-Lafitte.

On the outbreak of World War II all the great galleries and museums of Europe were closed, and many of their works of art were stored in secure hiding-places. Opportunities for holding large exhibitions were rare, although the Palazzo Venezia was used after the liberation of Rome for two exhibitions of masterpieces from the foremost Italian galleries. At the end of the war a number of outstanding exhibitions was held. There was an interesting display of modern tapestry in Paris, from where some of the work of Lurçat was sent to London in 1946. Among Viennese exhibitions was one of the work of Oskar Kokoschka.

(F. C. G.)

Art Galleries and Art Museums

Despite World War II, the decade from 1937 to 1946 was one of tremendous expansion in the museum world, not only in the erection of new buildings but in the acquisition of important collections and individual items.

The most outstanding event of the year 1937 was the offer on the part of Andrew W. Mellon to present his \$19,000,000 art collection to the United States and to build a \$10,000,000 building to house his as well as other great collections which might be offered to a national gallery. Included in the collection were paintings by such world famous artists as Van Eyck, Memling, Rembrandt, Vermeer, Van Dyck, Botticelli, Titian, Raphael, Chardin, Duerer, Velasquez and Goya.

Another notable gesture was made by Jules S. Bache, who offered his collection at 814 Fifth avenue to the state of New York. Particularly notable were paintings by Bellini, Raphael and Peter Christus. In quite a different vein was the establishment by Solomon R. Guggenheim of a Museum of Non-Objective Painting. This collection contained many fine examples of the work of Wassily Kandinsky, although the greatest representation was Rudolf Bauer.

Besides the founding of these three important public collections, several museums acquired paintings of exceptional merit. The Honolulu Academy of Art was too remote to figure often in U.S. news, but its acquisition

of Cézanne's "Girl with Doll" was heralded as an important event. An outstanding Flemish painting, Quentin Massys' "Rest on the Flight into Egypt," was added to the Worcester museum collection. The museum also acquired a celebrated painting by Piero di Cosimo, "The Discovery of Honey," executed in 1498 or soon after.

A notable 18th century French canvas, François Boucher's "Portrait of Mme. Boucher," was purchased for the Frick collection. Dated 1743, this delightful example of the art of an elegant century came from the famous David-Weill collection in Paris.

Thomas Hart Benton completed his murals of Missouri history for the capitol at Jefferson City. Probably no series of murals had ever been the subject of so much controversy.

The Boston Museum of Fine Arts purchased a great Renoir of 1883, "Le Bal à Bougival," sometimes called the "Dance in the Country." Luscious in colour, this full-length canvas shows a spirited young couple dancing gaily at an outdoor resort. The man is Paul Lhote.

The year 1938 was also significant for the increase of art collections available to the public. In Wilmington, the Delaware Art centre opened, featuring the Bancroft collection of Pre-Raphaelites, also a large group of paintings and drawings by the illustrator Howard Pyle.

An important event in museum expansion was the opening of the Cloisters, a branch of the Metropolitan museum, at Fort Tryon park in upper Manhattan. Gift of John D. Rockefeller, Jr., this \$2,500,000 building housed the collection purchased from the sculptor, George Grey Barnard, and the cream of the Metropolitan's mediaeval material. Rockefeller made a notable addition in presenting the six famous Unicorn tapestries.

Fragonard's "Portrait of a Lady with a Dog" and Ingres' grizaille "Odalisque" were the Metropolitan's most notable acquisitions in the field of painting. David's "Portrait of Countess Daru," from the David-Weill collection, was an outstanding addition to the Frick collection. The Rhode Island School of Design purchased "St. Peter's Flight from Prison" by Rembrandt's rare and talented pupil, Carel Fabritius. Picasso's famous painting of 1931, "The Mirror," was presented to the Museum of Modern Art by Mrs. Simon Guggenheim.

In 1939, the Museum of Modern Art moved to its new \$2,000,000 structure at 11 West 53rd street, designed in modern style by Edward Stone and Philip L. Goodwin. Movable partitions afforded flexibility in installation. The rear of the building, largely areas of solid glass, overlooked a sizable court in which sculpture was effectively displayed The museum's tenth anniversary was celebrated at the opening of the new building by "Art in Our Time."

Samuel H. Kress made the first of a series of gifts to the National gallery in Washington consisting of 375 paintings, largely early Italian, and 18 pieces of sculpture. The total valuation was estimated at \$25,000,000. The Museum of Fine Arts in Boston purchased an important painting by the great Venetian, Canaletto, called "The Bacino di San Marco." This came from Castle Howard, one of the great English collections.

Through the Edward Drummond Libbey fund, the Toledo museum acquired one of the best known Renaissance reliefs in existence, the "St. Cecilia" by Desiderio da Settignano. The Cleveland Museum of Art received, as a gift from Louis D. Beaumont, "The Minuet in a Pavilion" by Watteau. This outstanding 18th century French picture was formerly in the collection of Frederick the Great.

In 1940, José Clemente Orozco completed a six-part movable fresco for the Museum of Modern Art. The semi-abstract composition entitled "Dive Bomber and Tank" was designed so that the panels could be arranged in various ways to give different effects.

The most important event of the year 1940 in the museum world was the presentation of the Widener collection to the National gallery in Washington. As it constituted the most important group of works of art still in private hands, this gift on the part of Joseph E. Widener came as a munificent addition to the national collection. Chinese porcelains, furniture, tapestries, jewellery were included, as well as paintings, among which were two notable El Grecos, a "Madonna" and "St Martin and the Beggar," Vermeer's "Woman Weighing Pearls," Raphael's "Small Cowper Madonna," Rembrandt's "Mill."

On March 17, 1941, the National gallery opened formally with the Mellon and Kress pictures forming the nucleus. The Widener collection was not yet in their possession.

For many years the famed Johnson collection was housed in an old residence in downtown Philadelphia. There in a house that was far from fireproof the pictures could not be seen to advantage. It was, therefore, a matter of considerable interest to the art world when the collection was moved to the Philadelphia museum, where it was shown under favourable conditions. The collection did not, however, become the property of the Philadelphia museum, but retained its own identity.

The Museum of Fine Arts, Boston, purchased an enormous painting by Rubens depicting the "Head of Cyrus Brought to Queen Thomyris." Formerly in the collection of the Earl of Harewood, the painting, measuring 80x141 in., was executed in 1622–23.

Perhaps the most noted example in the world of intarsia or wood mosaic inlay is the small library or study, measuring 17x13 ft., which was executed between 1479–82 for Federigo da Montefeltro, duke of Urbino, a small but powerful Italian principality. This room was acquired by the Metropolitan museum from the palace at Urbino and is a unique example of 15th century woodwork Shelves of books, furniture and various small objects were represented so realistically with inlay of various types of wood that one had the illusion that these objects actually existed in the room.

In 1942, the National Academy of Design moved to new quarters at 1083 Fifth avenue, the former residence of Archer M. Huntington. The academy, founded in 1826, had a long and varied history and had included in its numbers the majority of the most notable men in the field of U.S. art. Samuel F. B. Morse, inventor of the telegraph, was the first president and Asher B. Durand succeeded him. "Our Heritage" was the title of a fine retrospective exhibition held as a feature of their opening.

In Terre Haute, Ind., the Swope Art gallery opened and dedicated its activities to the showing of contemporary U.S. art. Of a more sensational nature was the opening by Peggy Guggenheim of the Art of This Century, a gallery at 30 West 57th street, New York, devoted wholly to cubist, abstract and surrealist art. There all the most advanced creations of Dali, Max Ernst and many others could be seen in a setting which was itself unique.

Mrs. Ralph H. Booth presented to the Detroit Institute of Arts one of the most noted of Renaissance portraits, "Eleanor of Toledo" by Bronzino. The most elaborate and

Statue and fountain on the main floor of the National Gallery of Art at Washington, D.C. The gallery was a gift of Andrew Mellon and was dedicated by President Franklin D. Roosevelt on March 17, 1941

sumptuous costume was rendered with meticulous care. The Cleveland Museum of Art came into possession of the John L. Severance collection, one of the most astutely selected groups of furniture and paintings in the U.S., emphasizing the 18th century.

The most outstanding bequest of 1943 was the Grenville L. Winthrop collection which was left to the Fogg museum in Cambridge. Some 4,000 objects constituted this remarkable collection, composed of Chinese bronzes, Egyptian, Aztec and Mayan sculpture, an outstanding group of Pre-Raphaelite paintings and other important

pictures such as David's "Girl in White Dress." Winthrop was a man of extraordinary taste and wide interests.

George Blumenthal bequeathed his collection to the Metropolitan museum, whose president he had been. Paintings and decorative arts of the mediaeval and early Renaissance periods made up most of the collection. A new museum was opened at the Cranbrook Academy of Art at Bloomfield Hills, Mich., demonstrating again the importance of an active museum as an integral part of the art program in U.S. schools and colleges.

In Minneapolis the Walker Art centre was revived and modernized. Formed originally to house the collections of the Walker family, the gallery was reconstructed, all but their finest objects eliminated, and a program organized to emphasize contemporary art. New methods of installation were tried out, and fresh ideas about adult education were put into practice.

A great Veronese, the "Virgin and Child in Glory with Saints," was acquired by the Museum of Fine Arts, Boston. The Cleveland museum purchased a notable early Renoir portrait, "Mlle. Romanie Lacaux," painted in 1864, while the Albright Art gallery in Buffalo acquired "Le Chahut," one of four important oils in the U.S. by the noted French 19th century painter, Georges Seurat.

Three rooms at the Art Institute of Chicago were given over to an outstanding group of 20th century French paintings lent for an indefinite period by Chester Dale, the noted collector of modern art. Picasso, Braque, Modigliani, Matisse and others were shown in first rate examples.

Much activity went on at the Metropolitan museum in 1944, when it did over and reinstalled its galleries as a result of its finest possessions being returned from war storage. As a special precaution, the museum had sent its best material to a place of safety. Paintings were cleaned and reappeared in pristine condition. The Altman collection was moved so that it was placed in proper sequence in the painting gallery arrangement. The Jules Bache collection was turned over to the Metropolitan as it could be housed much more adequately there than in the old Bache mansion.

Thirteen pictures from the Maitland Griggs collection went to the Metropolitan. This exquisite group, for the most part composed of small early Italian pictures, contained such choice panels as the "Chess Players" by Francesco di Giorgio and Sassetta's "Journey of the Magi."

At the time of the famous Armory show of 1913, which was the first exhibition in the U.S. of international modern art of the most advanced sort, the most discussed painting was Marcel Duchamp's "Nude Descending a Staircase." This picture, as well as numerous other cubistic and abstract compositions, was acquired by Walter Arensberg, an astute collector living in Hollywood. His collection grew through the years and gained a just reputation as one of the very top groups of modern works. Arensberg announced that he had given his collection to the Los Angeles branch of the University of California.

Samuel H. Kress made another magnificent gift to the National gallery, 80 paintings and 26 pieces of sculpture. Covering various periods, the group included a Giotto "Madonna," Duccio's "The Calling of the Apostles Peter and Andrew," Sassetta's "The Meeting of St. Anthony and St. Paul," Raphael's "Bindo Altoviti," Tintoretto's "Christ Walking on the Sea" and Watteau's "Italian Comedians." Early Renaissance sculpture formed an important part of the group with such pieces as Verrocchio's "Lorenzo de' Medici" and two busts by Desiderio da Settignano.

In 1945, the Art Institute of Chicago greatly enriched its Kate S. Buckingham collection of mediaeval art with several notable purchases, among which were a "Head of Louis XI of France" (15th century), a 13th century Italian seated "Virgin," and a notable "Head of a Prophet," Ile-de-France mid-13th century.

Chicago also acquired the largest canvas in the U.S. by Chardin, "The White Tablecloth," a simply arranged, deftly painted still life dating from around 1730, and also purchased an imposing late Renoir, a "Seated Nude," of 1919.

A superb re-installation of the Greek collection opened at the Metropolitan museum. This collection, most important in the western hemisphere, now covered the entire history of Greek art from prehistoric times to the late classical and included masterpieces such as a full standing male figure, "Komos," of about 600 B.C., a superb bronze statuette of a horse dating from about 480 B.C., and an "Eros" of the Hellenistic period, 250–150 B.C. Vases, bronzes, jewellery and many other smaller objects were carefully selected and arranged to show the visitor in logical progression the development of Greek art.

The Cleveland museum purchased through the Grace Ramey Rogers fund a fine French portrait of 1795, David's "La Citoyenne Crouzet," showing his neoclassic style at its best. They also acquired "La Vie," a well-known Picasso of the Blue period, done in 1903.

A famous Fragonard drawing, "Les Pétards" (The Firecrackers), went to the Museum of Fine Arts, Boston. The Detroit Institute of Arts acquired an outstanding Flemish portrait, Mabuse's "Johann Ingenary, Abbot of the Monastery of Camp," dated 1535. A realistic portrait by Thomas Eakins, Mrs. Mary Hallock Greenewalt, was added to the collection at the Wichita (Kan.) Art museum.

A richly painted late Renoir, "The Young Shepherd," entered the Rhode Island School of Design in Providence. Painted in 1911 when the artist was over 70, it probably shows Alexander Thurneyssen, the younger son of a Munich doctor whom Renoir had recently visited. The Frick collection reopened with new hanging and many pictures freshly cleaned. Again the public was able to enjoy this splendid collection, well chosen by Henry Clay Frick.

The year 1946 closed a decade with continued munificence of gifts to museums and the announcements of future rebuilding and expansion. Samuel H. Kress for the third time became a great benefactor of the National gallery in Washington, presenting on this occasion 110 works of art. Among the paintings were Fra Angelico's exquisite "Healing of Donna Palladia by St. Cosmos and St. Damian," two Sassettas, two Botticellis, two Fra Filippo Lippis, three Bouchers, three Fragonards, Ingres, Chardin's wonderful "Portrait of an Old Woman." The famous "Capitoline Wolf," a Sienese 15th century bronze, was also part of the group.

After ten years of litigation, the Ringling museum at Sarasota was turned over to the state of Florida. With this went the home of the circus magnate, John Ringling, destined to be a Venetian museum. The two properties were reputed to be worth \$15,000,000.

A Duccio "Crucifixion," comparatively little known item in the J. P. Morgan collection, was added to Boston's Museum of Fine Arts.

At the Art Institute of Chicago an impressive array of some 60 drawings, nearly all later gifts and purchases, was opened in a specially designed setting. Highlights in the group were Canaletto's "Ruins of a Courtyard"

and Fragonard's "The Letter." Degas, Gauguin, Cézanne, Van Gogh, Picasso and numerous others were included in top quality examples.

Disposition of European art objects was a matter of great interest. More than 6,000 objects looted from France by the nazis were returned to the Rothschild and other collections. Paintings, sculpture, tapestries, silver and many other sorts of art objects from French collections were discovered in Schloss Neuschwanstein, built by mad King Ludwig II of Bavaria, at Fussen near Munich.

Two hundred and two paintings which formerly hung in German museums arrived at the National gallery in Washington for safe keeping until such time as conditions in Germany should warrant their return. The group, which included pictures by Fra Angelico, Botticelli, Duerer, Chardin, Holbein, Hals, Rubens, Rembrandt, Vermeer and Velazquez, was valued at \$80,000,000.

Museums throughout the U.S. contemplated building new wings and expanding in various ways as soon as building material became available. Elaborate plans were announced by the Metropolitan museum, which was working on a \$10,000,000 reconstruction project. The museum planned to divide its collections into five separate units: American art, oriental art, decorative arts, ancient art and a picture gallery. A special Whitney wing was to be constructed to house the Whitney Museum of American Art. In this way order and logic would be brought to a collection which had become too vast and unwieldy for its quarters. (F. A. Sw.)

Arthritis

Rheumatic disease, a general term including various forms of arthritis, is responsible for an appalling amount of invalidism. It was estimated that more than 320,000 persons in the United States alone were rendered unemployable for an entire year by these disorders. About one in each 1,000 persons in the U.S. was affected with some form of rheumatism on any one given day.

The greatest advance in the understanding of arthritis during the decade 1937-46 came from the recognition and differentiation of several types. A formal step in this direction was taken by the American Rheumatism association at its June 1941 meeting in the adoption of provisional classification: (1) specific infectious arthritis, where the causative organism is known; (2) arthritis of rheumatic fever; (3) rheumatoid arthritis (also called atrophic or chronic nonspecific infectious arthritis); (4) degenerative joint disease (also called osteoarthritis or hypertrophic arthritis); (5) arthritis of immediate traumatic origin; (6) arthritis of gout; (7) arthritis of neuropathic (nerve disease) origin; (8) neoplasms (tumours) of joints; and (9) miscellaneous forms (or arthritis associated with other disease). The developments of the decade can be best considered under the headings suggested.

Specific Infectious Arthritis.—The treatment of several of the types of arthritis falling in this group was revolutionized. Included are arthritis caused by the tubercle bacillus, the pneumococcus, gonococcus and streptococcus, called respectively, tuberculous arthritis, pneumococcal arthritis, gonorrhoeal arthritis and suppurative arthritis.

The treatment of tuberculous arthritis was not extensively modified. All three of the other varieties mentioned, however, were found to yield to treatment with the sulfonamide drugs or penicillin, or both. In fact, the results of treatment were little short of miraculous in most cases.

Consequently, the importance of early and accurate identification of the germ responsible for the arthritis of any of these varieties became even more important than in the past.

Another member of this group is the arthritis which frequently accompanies undulant fever or brucellosis. Brucellosis, caused by a specific germ and often associated with painful and inflamed joints, became increasingly widespread during the decade. The treatment for the arthritis of undulant fever was not always satisfactory; good results were reported from the use of a serum, a vaccine, and chemical agents of the sulfonamide group. Penicillin proved disappointing.

There are other types of joint disease caused by identified microbes, but those mentioned are the most common. Some of these other varieties also responded to treatment with the sulfonamides or penicillin.

Arthritis of Rheumatic Fever.—Painful and swollen joints usually accompany the disease called rheumatic fever. The cause of rheumatic fever still was not known, although it was the subject of extensive research, especially in the U.S. armed forces. The joint symptoms associated with the disease are usually severe, and the joints are swollen and painful, though permanent damage to them is rare. No specific treatment for rheumatic fever arthritis was developed; the use of salicylates (of which aspirin is the best known example) internally, and oil of wintergreen (another salicylate) externally was still the most favoured form of treatment.

Rheumatic fever and its joint symptoms tend to recur. Both the arthritis and the other symptoms often can be prevented from coming back by taking one of the sulfonamide preparations (usually sulfathiazole) by mouth over a long period. This did not seem to affect the arthritis directly but acted to cut down the number of infections of the throat causing a recurrence of the disease.

Observations made by the U.S. navy and army air forces in particular showed that rheumatic fever was much more common in certain localities than in others. During World War II it was decidedly worse in air force installations in the Rocky Mountain area than it was, for example, in southern camps. The reasons for this were not yet clear at the end of the decade.

Rheumatoid Arthritis.—Rheumatoid or atrophic arthritis is the variety of joint disease responsible for most cases of arthritis deformity and crippling. It is extremely widespread and accounts for a high percentage of all cases of rheumatic disease.

The cause of rheumatoid arthritis had not yet been discovered in 1946. It has many of the aspects of an infectious disease, but no germ or virus had been discovered which investigators could agree on as a definite cause. One of the greatest difficulties in investigating it was the fact that animals do not have any natural disease sufficiently similar to rheumatoid arthritis in human beings to serve as a real aid. Probably the closest approach to rheumatoid arthritis in animals is a spontaneous infectious polyarthritis in the rats of Java, which before World War II offered promise of yielding information of practical importance. Progressive arthritis resembling in certain respects human rheumatoid arthritis was produced experimentally in mice, who were given a viruslike microorganism obtained originally from a brain of a normal mouse. In both cases, however, later studies did not throw any new light of importance on the disease in human beings.

Although the causes of rheumatoid arthritis were not discovered, a great many interesting observations were made which eventually might help in solving the problems. It was noticed, for example, that patients with rheumatoid arthritis who became jaundiced are usually relieved of their joint symptoms for a period of time. Attempts were made to inject the bile salts causing jaundice into the patients with rheumatoid arthritis with the purpose of trying to alleviate their symptoms. This treatment was only moderately successful. It was found that when jaundice could be produced by this means the joints were usually improved, but the improvement did not generally outlast the jaundice very long.

Patients with rheumatoid arthritis in one group were found to have blood vessels which could be particularly easily constricted-this meant that the circulation in certain areas could be interfered with more easily than in normal persons. This observation suggested the reason why some persons may be particularly predisposed to rheumatoid arthritis or to flare-ups of the condition after they have had an emotional upset or have been exposed to cold. In another study several women with typical rheumatoid arthritis were placed under conditions which caused them to lose body water. The water loss caused a decrease in the joint pains and swellings, and the patients demonstrated an increased ability to move easily. When the process was reversed and the patients accumulated body water, the symptoms got worse. Emotional stress was known to effect the onset and course of arthritis in many patients. When the skin temperatures of a group of patients were recorded, emotional stress was found to produce a drop in skin temperature of just about the same degree in normal as in arthritis persons. This indicated that further study of the problem was necessary.

Increasing recognition was given to the fact that rheumatoid arthritis is a disease of the body as a whole rather than of the joints alone. With this came greater emphasis on treating the whole patient rather than just the joints. The sulfonamide drugs and penicillin were tried but did not prove at all effective. During the decade, treatment with gold salts by injection received a great deal of study. The evidence indicated that gold salts are effective in a good many people and bring about considerable relief of symptoms. Unfortunately, however, the salts are toxic and dangerous, and severe reactions were observed. Until less dangerous gold salts than those on the market were developed, this form of treatment probably would not be widely used. A synthetic drug known as neostigmine was tried in rheumatoid arthritis as well as in a variety of other diseases involving spasm, tension and spasticity of the muscles. This drug was reported as having value in relieving the muscular tension and some of the pain connected with rheumatoid arthritis, but it did not act on the inflamed joints themselves.

Increasing recognition was given to the need for adequate institutional care for patients with chronic arthritis, especially of the rheumatoid variety. In Sweden, for example, state pensions were granted workers for permanent incapacity caused by chronic articular rheumatism. In the U.S. the need for institutions for chronic invalids and for the establishment of a dispensary organization for rheumatic patients was stressed.

Degenerative Joint Disease.—Although degenerative joint disease often goes by the name of osteoarthritis or hypertrophic arthritis, true inflammation in the joint is usually absent. Investigations showed that prolonged injury to or excessive use of the joints is likely to result in some enlargement of the bone around the joint which is

the principal characteristic of this disorder. A study of cattle, for example, indicated that degenerative changes of the bone were much more common in those joints which received excessive use and minor injury than in those joints not used so hard. The enlargement of the end joint of the little finger commonly seen in baseball players and caused by repeated injury, is almost exactly similar to the ordinary forms of degenerative joint disease. Consequently, during the decade, the part played by chronic injury, whether by ordinary use or special damage, came to be recognized as an important if not the most important cause. When inflammation of the joint does develop, it is more commonly caused by irritation of the joint membranes from the enlarged bone rather than by any bacterial or infectious process, such as is present in true arthritis.

Little was discovered about treatment of degenerative joint disease. If the theory as to its origin was not disproved, the treatment would be likely to consist in prevention of further injury, so far as possible. It was unlikely that any method would be found soon of dissolving the excess bone formation without injuring the normal bone structure.

Arthritis of Immediate Traumatic Origin.—Traumatic joint disease occurs most frequently as a result of injury from athletic sports; about half the cases come from strains of the ligaments and the remainder from bruises to the joints, muscles or bursas, or damage to the cartilages lying deep in the joint itself. Treatment of the strains and bruises is aimed at decreasing the amount of bleeding. Early application of ice water to the injured part, followed by a sponge rubber type bandage and rest was suggested. Later treatment consisted of heat, gentle massage and early mild exercise with the joint supported by a compression bandage. For the cure of deep injuries, the most common of which is "internal derangement of knee joint," operation was usually necessary.

Arthritis of Gout.—Gout is a disease which, if it continues for a long time, may cause chronic inflammation in a joint or joints. During the decade there were many articles on the subject which indicated that gout is not as rare as generally believed. Consequently, it may be a more important cause of arthritis than is usually recognized. There were no outstanding discoveries on the cause or treatment of gout during the decade, but its recognition as a cause of joint trouble seemed to be important.

Arthritis of Neuropathic Origin, Neoplasms and Miscellaneous Forms.—Certain diseases affecting the nervous system result in changes in the joints; such changes are called neuropathic arthritis. Inflammation may or may not be present, but occasionally the joint changes are remarkable in size and extent. The treatment is, of course, directed at the cause when the latter can be identified. As a rule, however, the changes which have developed in the joints are irreversible.

Neoplasms or tumours of the joints are rather rare, but do occur. What they cause in the joints should not properly be called arthritis, although secondary inflammation is sometimes present. The treatment is directed at the tumour and includes surgery, X-ray or radium.

There are a considerable number of diseases or miscellaneous conditions which can cause joint disturbance. This group includes some joint diseases of unknown cause, as well as the joint symptoms which accompany well known disease entities. Among the most interesting joint disorders in this group is a disease which has been called palindromic rheumatism, a recognized oft-recurring disease of the joints. The outstanding features of this condition

are repeated attacks of acute arthritis involving several joints not accompanied with fever. The joints become painful, swollen and red. The attacks develop rapidly, last only a few hours or days, and then disappear completely, only to come back again and again at irregularly spaced intervals. In spite of the acute inflammation in the joints, the condition does not seem to harm the joints permanently, and abnormalities cannot be discovered even after hundreds of attacks.

Another important joint disorder of rather uncertain classification is a condition of the joints of the spine, called spondylitis. Some felt during the decade that this is really only one variety of rheumatoid arthritis, but the point was not settled. It is a condition affecting men—usually young men—much more frequently than women—the reverse of the usual type of rheumatoid arthritis. It is a gradually progressing disease often called "poker spine." The cause of this disease also had not been discovered during the decade, and little was known as to its genesis. Some studies indicated that X-ray treatment is the most effective. Although X-ray treatment does not always bring relief, it was probably the most important development of the period in the treatment of spondylitis.

* * *

THE TYPE of arthritis which most needed investigation at the end of the decade was the rheumatoid. The cause of rheumatoid arthritis was yet to be discovered; an experimental animal which could be used satisfactorily to increase the knowledge about this disease had not been found. Also, no sure cure for rheumatoid arthritis was yet available. In spite of failure to solve all the problems of arthritis during the decade, however, great progress was made. The principal feature of this progress was the division of arthritis into more clear-cut groups, some of which could be promptly and successfully treated. Also important was the recognition of degenerative joint disease as caused principally by use and injury rather than inflammation. Treatment of certain varieties of arthritis of known cause with the sulfonamide drugs and with penicillin represented a great advance. The use of gold salts, especially if non-toxic preparations could be developed, offered considerable hope for the treatment of patients with rheumatoid arthritis. The X-ray treatment of arthritis of the spine, or spondylitis was also a promising new method of treatment.

Art Sales

The sales rooms of art saw a spectacular increase in their business, unequalled in their history, during the decade 1937-46. A basic reason could be found in the fact that within that period the United States went from a major depression, with its accompanying shortage of cash and lower prices, to a major world war, with the resulting large incomes and high prices. Many secondary factors had also to be taken into consideration. With the great increase in inheritance taxes, many collections were sold, since heirs preferred to take advantage of high prices rather than be subject to high taxes. As automobiles and many luxury goods went off the market and travel was restricted, those in comfortable income brackets looking for a place to spend their money found the auction rooms enticing. High prices were no deterrent, since there was always the prospect that they were going still higher.

The presence of many discriminating collectors from Europe also stimulated competition in the salesroom. Accustomed to the drastic fluctuation of currency in Europe, they knew even better than Americans that a fine work of art was a good investment. Throughout the country there was a rising interest in art; more and more people developed discriminating taste; they went to the auction rooms in ever-increasing numbers and with greater understanding of what they were buying. Anything of quality inevitably brought a good price. Auction statistics, announced every summer, covered the previous season rather than the calendar year. In 1937, the leading New York auction house was the American Art Association-Anderson galleries, which did an unusually good business in the 1936-37 season because of the Brady sale. Their total amounted to \$2,970,997, of which \$471,761 came from the sale of the 86 room Long Island mansion, Inisfada, and contents, property of Mrs. Nicholas F. Brady (Mrs. William J. Babington Macaulay). Two Tournai tapestries brought \$43,000.

The Parke-Bernet galleries were organized in Jan. 1938, and in their first season did a \$1,250,000 business. Total for the American Art Association-Anderson galleries was \$2,000,000, of which \$535,220 represented the sale of the Cortland F. Bishop library. This was their last season and the following year they were succeeded by Parke-Bernet as the leading auctioneers. The Plaza auction rooms, a smaller firm, continued to operate, doing a business of \$681,701 in 1938.

Auction trends after 1938 could best be followed through the statistics of Parke-Bernet, which in 1939 showed a total of \$2,417,330. Their two largest items were a portion of the William Randolph Hearst collection which brought \$393,796.50 and the John A. Spoor library, \$181,510. Their 1940 season was about the same, \$2,329,330.50 with Mrs. Cornelius J. Sullivan's sale as the highlight. Van Gogh's "Mlle. Ravoux" brought \$19,000.

By 1941 the rise in prices was beginning to be felt. Parke-Bernet totalled \$3,606,881.75, the largest amount after 1929. Mrs. Henry Walters' sale came to \$646,684,

WPA art project paintings were sold for a few dollars each at a secondhand shop in New York city in 1944. Purchased from a government warehouse for four cents a pound after the liquidation of the project, they represented the work of numerous artists during the depression years

and in the J. Horace Harding sale were several notable paintings including Goya's "Victor Guye" at \$34,000.

By 1942 Parke-Bernet totalled \$4,007,823, their highest single item having been \$39,000, paid for John Hoppner's portrait of Miss Frances Beresford. Gimbel's department store had taken advantage of the lucrative art market and through their auctioneers, Kende, amassed \$5,255,000. A good portion of this came from the sales of the Bliss collection and Clarence Mackay collection. Late in the year Kende took over the old Jay Gould mansion on Fifth avenue as a centre in which to hold their auctions.

The 1943 season was slightly less but still far above the average. Parke-Bernet totalled \$3,611,847. Highest single sale was the Mr. and Mrs. Charles E. F. McCann collection which amounted to \$266,207, and included furniture, ceramics and silver. A gold tea service which had belonged to Paul I of Russia brought \$11,000. The Wadsworth Lewis sale was second at \$187,238. Individual pictures brought good prices, Renoir's "Fleur et Chats," \$34,000, and Frans Hals's "The Rev. Caspar Siblius," \$30,000. Kende gallery, including floor sales at Gimbel's, totalled \$4,225,000. A Cuyp landscape brought \$8,700 and a Rosa Bonheur \$7,600.

A great rise was noted in 1944, the first year of the great art boom. Parke-Bernet's total reached \$6,156,632.50. Kende's, including the Hearst sales at Gimbel's, brought \$4,100,000, and the Plaza auction galleries, \$1,196,812.70. This made a total of nearly \$11,500,000. Parke-Bernet alone had an attendance of just under 200,000. The stock of Yamanaka brought \$466,971.50, the J. P. Morgan sale, \$400,540, John R. Thompson sale, \$262,780. In the last was Frans Hals's "The Merry Lute Player," which brought the top price of the season, \$127,000. Corot's "La Grande Métaire" brought \$20,000, Manet's "Le Petit Lange," \$18,500, and furniture, with \$4,200 for a pair of Chippendale chairs, was also at a new high.

The art market continued to flourish during 1945. Parke-Bernet reached \$6,165,920.50 and Kende \$3,635,275. At Parke-Bernet, the William H. and Cornelius Vanderbilt sale totalled \$323,195 and indicated the renewed interest in the Barbizon school and other 19th century painters long out of favour. Millet's "Water Carrier" tied with a Fra Filippo Lippi "Madonna" for \$30,000. Millet's "The Sower" was bought for \$26.000 by the Provident Trust company, since it was the original of their trademark. A Boldini went for \$6,000 and a Gerome for \$5,700. Kende's top sale was Tintoretto's "The Baptism of Clorinda" at \$41,000. Frederic Remington's "A Dash for Timber" brought the astounding price of \$23,000.

Parke-Bernet's 1946 record made auction history with an all-time high of \$6,684,045. The Isabel Van Wie Willys collection brought \$594,902. A portion of the collection of the late Sir William Van Horne, Canadian railroad magnate, went for \$221,500. A notable library of early English books, belonging to Frank J. Hogan, brought \$209,888. The Marion Davies and Walter P. Chrysler, Jr., collection's were others fetching high totals. The highest individual price was \$75,000 paid by Billy Rose for Rembrandt's "Pilgrim at Prayer." Toulouse-Lautrec's "Gueule de Bois" brought \$30,000, and Ryder's "Siegfried and the Rhine Maidens," \$23,500. Popularity of genre painting was indicated by the fact that Fortuny's "Breakfast at the Alhambra" went for \$5,200.

The Plaza galleries, always on a more modest scale, totalled \$1,441,471.95 with \$7,200 for Greuze's "Portrait of a Child" their top single price. Kende sold Sorolla's "Andalusian Dancers" for \$4,700, another return to popularity of an artist out of favour. (F. A. Sw.)

Asbestos

The asbestos production of the major producing countries, so far as data were available at the end of the decade 1937–46, is shown in the accompanying table.

Wor'd Production of Asbestos (Thousands of short tons)

193 <i>7</i>	1938	1939	1940	1941	1942	1943	1944	1945
Canada 410.0	289.9	364.5	345.8	477.8	439.5	467.2	419.3	460.1
Cyprus (exp.) 13.1	6.2	11.4	10.7	5.4	3.9	1.4		
Italy 7.0		7.5	9.1	11.9	12.9			
South Africa 28.6	23.2	22.1	27.4	28.3	34.6	35.6	34.6	21.8
South Rhodesia 57.0	58.8	58.3	57.9	54.2	62.3	56.4	58.3	56.3
Swaziland		8.0	20.8	21.1	25.6	18.9	32.7	
United States 13.9	12.9	15.1	19.2	22.4	15.3	3.9	7.6	13.6

Data were too incomplete to permit the accumulations of world totals during the war years, but the total was of the order of 675,000 short tons in 1937. Except for the soviet union, with an output estimated at 138,000 tons in 1937, production from countries not listed was small. Lacking world totals, the trend in output could be judged only from the totals of the major producers, as listed in the table. War demand offset the 25% drop caused by the 1938 business recession, but it was not until 1941 that the 1937 level was passed, but then by a margin of 18%. Subsequent years brought declines, but 1945 rose to the 1941 level.

The Canadian output was irregular, with alternations of high and low figures each year after 1937, and after 1941 each high or low was less than the one preceding, marking a definite downward trend. However, in the first half of 1946, production was 250,217 tons as compared with 460,051 tons in 1945 and the previous record high of 477,846 tons in 1941. Although the bulk of the Canadian output continued to be exported, domestic consumption in the production of asbestos products had more than doubled after 1937.

In Southern Rhodesia, production fluctuated little, with the greatest activity in 1942. War demand for the special grades found only in South Africa kept output increasing until 1943, with a minor decrease in 1944; however, the 1945 production dropped to less than that of 1938 and 1939. Although Swaziland first appeared in the list as a new producer in 1939, with 7,973 tons, output increased consistently, and in 1944 was only a trifle less than in South Africa.

Italian production was stimulated by war demand up to 1942; later data were lacking, but the industry probably suffered when the fighting reached Italian soil. Production in Cyprus gradually waned, and considering the conditions prevailing in the Eastern Mediterranean during these years, it was surprising that mining could continue as long as it did.

The United States remained the largest consumer of asbestos, but had never had a significant output. Production nearly doubled under war demand, to a high of 22,396 tons in 1941, and after a sharp decline in 1942 and 1943, came back to the 1939 level in 1945.

The relatively small domestic output of the U.S. furnished only a small fraction of the consumption demand, most of which was supplied by imports—chiefly from Canada, South Africa and Rhodesia. Imports rose from

307,188 tons in 1937 to a high of 419,242 tons in 1942, and declined to 374,199 tons in 1945.

Aside from the acceleration in demand for asbestos in its ordinary applications (brake linings, pipe insulation, building materials, etc.) there were a number of more specific military uses. Long fibered Rhodesian chrysotile, low in iron, was required for woven electrical insulation for naval and aircraft use. South African amosite was used in heat insulation of low weight per cubic foot, and South African crocidolite, or blue asbestos, used in fabricating asbestos-cement pipe, made more iron available for war uses.

Asphalt

The production of natural and manufactured asphalts in the United States during 1937-45 is shown in the table.

Under normal conditions paving had taken most of the bituminous rock, petroleum asphalt and road oil, with roofing the second largest consumer of petroleum asphalt. During the early years of World War II much of the paving demand was restricted to divert the materials into airport runways. Normally imports of all types of asphaltic materials were around 100,000 tons a year, while exports

U. S. Production of Asphalt, 1937-45

	Natur (Thousands of		Manufactured (Barrels)			
	Bituminous Rock	Gilsonite	Petroleum Asphalt	Road Oil		
1937	447.213	38,038	4.181.988	8,087,231		
1938	449.091	28,574	4,506,900	7.788.000		
1939	422,484	37,289	4.954.200	7,868,000		
1940	458,665	31,930	5,346,700	7,769,000		
1941	654,692	36,407	6.557.600	9,149,000		
1942	935,295	40,041	6.296.500	8,039,000		
1943	835,648	50,446	6.756.700	2.295.000		
1944	740,454	49,051	6.996.100	1,556,000		
1945	642,600	61,273	7,126,600	5		

were more than double that figure. During World War II the figures were approximately reversed.

Assassinations

Following is a list of the principal actual and alleged assassinations of the years 1937–46 inclusive:

Ananda Mahidol, king of Siam, found shot in the royal palace at Bangkok on June 9, 1946; an investigation board later pronounced his death as probable assassination.

Andrews, Lewis Yelland, district commissioner of Galilee; shot fatally with his bodyguard, Constable Peter R. McEwan, at Nazareth, Palestine, on Sept. 26, 1937.

Barthélemy, Georges, former French Socialist deputy

who later became one of Pierre Laval's chief henchmen in the Vichy government; according to the Germancontrolled Paris radio, he was assassinated by "terrorists" in Paris on July 10, 1944.

Boris III (q.v.), king of Bulgaria, who died after a brief illness Aug. 28, 1943, at Sofia. The official statement attributed his death to a heart attack, but it was widely rumoured that he had been assassinated.

Calinescu, Armand, Rumanian premier; slain by six members of the fascist Iron Guard at Bucharest on Sept. 21, 1939. Hundreds of Iron Guardists were executed or imprisoned in reprisal.

Chang, Samuel H., director of the U.S.-owned Post Mercury company and two Chinese newspapers; assassinated by a gunman in the International zone, Shanghai, on July 19, 1940.

Darlan, Jean (q.v.), French naval officer, politician and vice-premier of the Vichy government before his political agreement with the Allies following the North African invasion of Nov. 1942; he was shot and killed by a young Frenchman in Algiers on Dec. 24, 1942.

Dormoy, Marx, French Socialist leader and interior minister in the Popular Front cabinet of Léon Blum; killed in explosion of time bomb set in his room by unknown persons near Montelimar, France, on July 26, 1941.

Fu Hsiao-en, Japan's puppet mayor of Shanghai; assassinated while asleep in his home on Oct. 11, 1940.

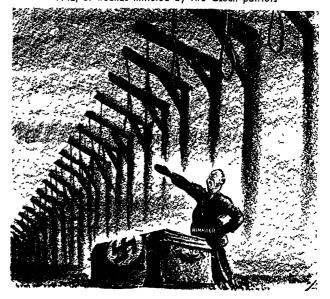

Haidar, Seyyid Rustum, Iraqi minister of finance; shot by a dismissed police inspector on Jan. 18, 1940, at Baghdad, Iraq, and died of his wounds four days later.

Henriot, Philippe (q.v.), French fascist and minister of propaganda in the Vichy government; shot and killed by French patriots disguised as policemen, in his home at Paris on June 28, 1944.

Heydrich, Reinhard (q.v.), called "The Hangman," German reich's protector for Bohemia and Moravia; he was shot by two gunmen while riding in his automobile on the Prague-Berlin highway on May 27, 1942, and died in Prague on June 4. In retaliation, the Germans slew many Czechs and razed the village of Lidice, where the assassins were suspected of having taken refuge.

Janeff, Sotir, pro-nazi president of the Bulgarian parlia-

Biting retort by Lewis in the Milwaukee Journal, to Heinrich Himmler's elegy of Reinhard Heydrich as a "character of rare beauty." Heydrich, known throughout Europe as "the hangman" died June 4, 1942, of wounds inflicted by two Czech patriots

Leon Trotsky on his deathbed in a Mexico City hospital Aug. 21, 1940. His assassin, according to Trotsky's associates, was an agent of the Russian O.G.P.U.

ment's foreign affairs commission, editor of the semiofficial *Slovo* and adviser to King Boris III; killed by two gunmen in Sofia on April 15, 1943.

Jorga, Nicolas, former premier of Rumania; slain by Iron Guardists in Bucharest on Nov. 28, 1940.

Maher Pasha, Ahmed, Egyptian premier; shot and killed shortly after he had read a royal decree declaring war on Germany and Japan, in the parliament building at Cairo on Feb. 24, 1945.

Marriner, James Theodore, U.S. consul at Beirut, Syria; slain by a crazed Armenian in Beirut on Oct. 12, 1937.

Moffatt, W. S., British assistant district commissioner; slain by an Arab gunman in Jerusalem on Aug. 25, 1938.

Monck-Mason, George E., British consul at Mosul, Iraq; slain by mob at Mosul on April 4, 1939, after rumor that King Ghazi, killed in a motor accident, had been slain by the British.

Moyne, Lord, British resident minister for the middle east; shot by two Jewish Palestinian terrorists, in Cairo, Egypt, on Nov. 6, 1944.

O'Dwyer, Sir Michael, retired British administrator in India; shot fatally by an East Indian at a public meeting in London, on March 13, 1940. The assassin also wounded Lord Zetland, secretary of state for India, and Sir Louis Dane and Lord Lamington, both former British administrators in India.

Osman Pasha, Sir Amin, former Egyptian finance minister; killed by a gunman in Cairo on Jan. 5, 1946.

Paringaux, Yves, French chief of staff of the Vichy government's interior ministry who directed suppression of anti-nazi activities; his body was found on a railroad track at Melun, France, on Jan. 5, 1942.

Peyeff, Yordan, Bulgarian army chief of staff; shot and killed by a Macedonian terrorist who then committed suicide, at Sofia on Oct. 9, 1938.

Rath, Ernst vom, third secretary of the German embassy in Paris; shot in the embassy on Nov. 7, 1938, by Herschel Grynszpan, a young Polish Jew, and died two days later in Paris. His assassination was followed by a renewed outburst of anti-Semitism in Germany.

Sidqi Pasha, Baqir, dictator of Iraq, assassinated by a

soldier in Baghdad on Aug. 12, 1937. Also slain was Major Mohammed Ali Jawdat, commander of the Iraqi air force.

Tang Shao-yı, first premier of the Chinese republic; assassinated in Shanghai on Sept. 30, 1938.

Tcheng Loh (Ch'en Lu), foreign minister in the Japanese puppet government at Nanking; shot fatally by some 20 Chinese assailants in Shanghai on Feb. 20, 1939.

Tresca, Carlo, anti-fascist leader and editor of an Italianlanguage weekly in New York city; shot and killed as he was leaving his New York office, on Jan. 11, 1943.

Trotsky, Leon (q.v.) (Lev Davidovich), Russian politician who fled the soviet union and ultimately took refuge in Mexico; attacked fatally by a man whom he described as an agent of the Russian secret police, in Mexico City, on Aug. 20, 1940. Trotsky died of his wounds the next day. The assassin gave his name as Frank Jackson but was identified as Jacques Monard van den Dresched.

Villarroel, Gualberto, president of Bolivia; killed by Bolivian student revolutionaries, at La Paz, on July 21, 1946. He was shot after being hurled from a balcony of the presidential palace; his body was then hung from a lamp post in an adjacent plaza.

Astronomy

The establishment of a new observatory, always an event of interest to astronomy, is of particular interest when two great universities combine their resources to establish one of the foremost observatories of the world. The dedication of the McDonald observatory in May 1939, celebrated the successful result of such a co-operative effort. Located in northwestern Texas, the McDonald observatory was built by the University of Texas and staffed by the University of Chicago. The 82-inch reflecting telescope, with numerous improvements in design and operation, was attested by experts to be one of the finest ever constructed. An idea of the superb quality of this great telescope was supplied by the fact that the distinguished double star observer, Georges Van Biesbroek, was able to measure successfully the separation of some of the closest visual double stars with it. The announcement of this feat occasioned surprise among astronomers, since it had been thought that large reflectors were poor instruments to use for this exacting type of visual observation.

Two other important new observatories were established during the decade 1937–46. Mexico's new astrophysical observatory at Tonanzintla was dedicated in Feb. 1942, equipped with a 27-31-inch Schmidt telescope and favourably situated for observations of the southern sky. The new astrophysical observatory of Haute-Provence in southern France was placed in operation during 1945, equipped with a 47-inch telescope and auxiliary instruments for investigations in the field of stellar and nebular spectroscopy.

Successful development of the Schmidt telescope as a powerful tool in astronomical research was shown by the installation of three telescopes of this type in the United

Dedication of McDonald observatory, on Mount Locke, Tex., May 5, 1939, with 400 distinguished guests attending

States (at Mt. Palomar, Calif., Harvard, Cambridge, Mass. and Case School of Applied Science, Cleveland, Ohio) as well as the excellent instrument at Tonanzintla. These telescopes made use of a spherical mirror and correcting plate instead of the usual parabolic mirror, and gave a wide-angle field in good focus. Their high speed was indicated by the fact that a good picture of a comet could be obtained in such a short time that the star images were not drawn out into trails. This speed made them useful for small cameras as well as for larger instruments, and they were successfully used in stellar spectrographs. This has a very special advantage when a spectrograph is used with a large reflector. All optical elements are then mirrors except for the correcting plate of the Schmidt. If this plate is made of quartz and all the mirrors are coated with aluminum, the instrument becomes very fast and efficient for spectral observation in the ultra-violet.

A distinctive new instrument for solar research was developed at McMath-Hulbert observatory, near Pontiac, Mich., where a new 70-foot tower telescope specially designed for photographing solar phenomena was installed. This new tower telescope was equipped with a spectroheliograph and numerous automatic devices for the efficient photographing of prominences and other solar phenomena on cinema film. It gave a two-dimensional

picture of a solar prominence while a second tower telescope, formerly used for this purpose, could be used to obtain velocities of the gases toward or away from the observer. Thus simultaneous observation with the two telescopes yielded a record of the motions of the gases of a prominence in three dimensions. This made possible the construction of three-dimensional models of some of them.

The Solar System.—Bernard Lyot, working at the Pic du Midi in France, obtained motion pictures of solar prominences by a technique different from that used at McMath. Instead of using a spectroheliograph, Lyot recorded direct photographs of the prominences on motion picture film with the same ingenious telescope (coronagraph) used for photographing the corona without an eclipse. This new method met with such success that Lyot further improved his observing technique by mounting a special polarizing device on his telescope. Using appropriate filters he was then able to photograph prominences simultaneously in three colours.

A by-product of Lyot's studies of the corona was the measurement of 22 spectral lines produced in this portion of the solar atmosphere. Identification of these and other coronal lines was one of the great unsolved problems relating to the solar spectrum. It was known that these lines must be produced by familiar chemical elements which existed under unusual conditions. Bengt Edlén made a systematic study of the spectra of highly ionized

atoms and was able to identify 15 of the coronal lines which, it was estimated, supply approximately 97% of all the radiation received from the corona. Edlén found that seven of these lines were produced by highly ionized iron, six of them by highly ionized nickel, and two by highly ionized atoms of calcium. Some of the lines had not yet been measured in the laboratory, but enough was known about the ionized states of these atoms from Edlén's studies to make his identifications reasonably certain. The other seven lines measured by Lyot and an additional seven new coronal lines measured by Donald H. Menzel and Robert M. Petrie on plates obtained at the total eclipse of the sun in 1936 remain unidentified. It was quite certain, however, that they were also produced by known chemical elements in a high state of ionization.

Two astronomers gained unusual distinction while observing the total solar eclipse of June 8, 1937. The path of totality crossed the Pacific ocean, touching no land except a few small islands until it reached the coast of Peru just before sunset. J. Q. Stewart and J. A. Stokley observed this eclipse from the deck of a freighter which was moving along the central line of totality and in the direction of motion of the shadow. The eastward motion of the ship lengthened the time they were able to observe totality by four seconds. They timed the duration of totality as 7 min. 6 sec. and thus had the distinction of seeing a longer totality than anyone before them.

The eclipse of July 9, 1945, was observed by more astronomers, professional and amateur, than any other total eclipse for many years. Astronomers from observatories of the U.S. and Canada and many co-operating amateurs were scattered along the path of totality in North America. Several groups of European astronomers observed the eclipse from northern Sweden, and more than 20 groups of soviet astronomers were located along the eclipse path in the U.S.S.R. The most spectacular expedition for the observation of this eclipse was that conducted by the Royal Canadian Air Force under the leadership of Peter M. Millman. Four air force planes carrying eight cameras made flights through the path of totality. Three of the cameras had objective prisms mounted in front of the lenses and recorded excellent pictures of the flash spectrum. The preliminary reports indicated that this operation was the most successful attempt yet made to photograph the eclipsed sun from aircraft.

The law of limb darkening of the sun continued to be difficult to determine. Many measurements of solar limb darkening were made without an eclipse, but these were inevitably affected by unsteadiness of the solar image produced by the atmosphere of the earth. Measurements of brightness of the crescent phases of a total solar eclipse obviated this difficulty because the occulting disk was then the moon, with its sharp edge, rather than a disk in the observer's telescope. The results of observations of limb darkening at the total eclipse of 1936 were published in 1941 by J. G. Ferwerda, J. Uitterdijk and A. J. Wesselink. They used an exceptionally ingenious photographic method to make their measurements. Ordinary spectacle lenses with different radii of curvature were aluminized on the convex surface and mounted on a board; when photographed with motion picture cameras these lenses gave images of the crescent sun in different densities. Careful measurements of the photographs indicated that the brightness close to the limb of the sun varies approximately as the tenth root of the distance from the limb. Nearer the centre of the solar disk the brightness was found to vary as the cube root of this distance.

Measurements of the colour of the thin solar crescent during the last minute before totality at a time when the light received is only 1/100th of full sunlight showed that there was no change of colour. This constancy of colour could be explained by the existence of a nearly isothermal layer near the surface of the sun. Rupert Wildt reached a similar conclusion as a result of his thorough analysis of the large collection of flash spectra obtained by S. A. Mitchell at a number of total eclipses.

For many years students of the solar spectrum had to depend on estimated intensities of the Fraunhofer lines, principally on the estimates of H. A. Rowland. The scale of intensities given by Rowland was carefully calibrated, and intensities of a few hundred of the stronger Fraunhofer lines had been measured with considerable precision. In 1941 M. Minnaert and his colleagues at Utrecht published a Photometric Atlas of the Solar Spectrum. This prodigious volume contained 174 pages (more than 300 feet) of microphotometer tracings of the sun's spectrum on a direct-intensity scale. The tracings covered the spectral region λ_{3332} to λ_{8771} with a scale of approximately 2 cm./A. From them, wave lengths based on the Revised Rowland Table could be read with an accuracy of about 0.01 A. Central intensities read from the Atlas were correct to about 5%. The value of this great piece of work to spectroscopists could not be overestimated.

Identification of the spectral lines of two more chemical elements in the solar spectrum—thorium and gold—was announced by Charlotte E. Moore and A. S. King in 1943. With their detection the number of chemical elements identified in the solar atmosphere was raised to 66. Thorium was the first radioactive element to be detected in the sun's atmosphere.

The existence of chemical compounds in the solar atmosphere had long been known, but few could be identified because of insufficient laboratory data about the spectra of the compounds. The characteristic spectral bands were exceedingly complicated for many of the molecules. In the solar spectrum there was considerable overlapping of these bands in addition to the fact that they were superimposed on a very rich atomic spectrum, making their identification very difficult. In 1945 Harold D. Babcock succeeded in identifying the bands of 18 compounds in the spectra of both sunspots and the solar disk. Of these 18, the 7 compounds not formerly identified were BH, MgF, SrF, YO, ScO, MgO, O₂. There still remained numerous unidentified molecular absorption bands in the spectra of sunspots.

Observers of the sun using spectrohelioscopes had frequently seen the development of bright patches much more brilliant than the surrounding solar disk. These bright solar outbursts, involving no observable motion of material, were called solar flares. As early as 1931 George E. Hale had noted that these flares often preceded brilliant auroral displays and widespread magnetic storms. He concluded that there was probably a distinct connection between flares and the terrestrial phenomena which succeeded them. In 1944 a thorough study of the relation between solar flares and magnetic storms was made by H. W. Newton. He showed that many flares observed within 45° of the centre of the sun's disk were followed approximately a day later by intense magnetic storms, and that the number of these storms which followed flares was greater than could occur by chance. He assumed that a stream of corpuscles is ejected from the sun when a bright solar flare is observed and that this corpuscular stream

travels out into space until it strikes the earth and produces a magnetic storm. From a study of the intervals of time between the appearance of flares and the occurrence of a magnetic storm, Newton determined the mean effective time of travel of the corpuscular stream to be about 26 hours. In the case of the most intense magnetic storms, a shorter travel time of about 20 hours was found. E. A. Milne's theoretical work on the ejection of high-speed atoms from the sun, produced by radiation pressure, had indicated a travel time for these atoms from the sun to the earth of 1.1 days. A comparison of these results would seem to indicate that the assumptions on which Milne's theoretical work was based were substantially correct. Newton found that the very intense magnetic storms were associated with flares occurring on the preceding side of the sun's central meridian, and suggested that the streams which produce these storms mostly strike the earth "head on." He found that the smaller magnetic storms tend to recur at intervals of a solar rotation and assumed that in this case the corpuscular stream was ejected more or less continuously over a considerable period of time. The stream would then partake of the solar rotation and overtake the earth in its orbit.

The light of the aurora most frequently observed had been that produced by an emission line in the green region of the spectrum. In 1945 Joel Stebbins and A. E. Whitford discovered a new auroral radiation in the infra-red. Found in the course of precise photometric observations of stars and nebulae, the new radiation was far more intense than the familiar green line. It was shown to be atmospheric in origin and to have an approximate wave length of 10,440 A. Strangely enough, no correlation was observed between this radiation and magnetic disturbances such as are usually found during auroral displays. P. Swings identified it as probably being due to emission of the (O, O) band of nitrogen. He suggested that nitrogen molecules, and compounds containing nitrogen atoms, are dissociated into nitrogen atoms by the absorption of ultraviolet solar radiation during the day. The nitrogen atoms would recombine during the night, chiefly in three-body collisions of two atoms and a nitrogen molecule. Such a collision would yield one normal and one excited nitrogen molecule, and the excited molecule would then emit the observed infra-red radiation. It was well known that nitrogen molecules are a major constituent of the earth's atmosphere at any altitude, and Swings' suggested mechanism of emission offered a plausible explanation of the observed infra-red radiation.

On Oct. 28, 1937, K. Reinmuth at Heidelberg discovered a fast-moving object of the tenth magnitude. Its hourly motion across the sky was approximately two-thirds of the apparent diameter of the moon. This motion was so rapid that American observers had difficulty in locating it, and only a few observations of this object were obtained. The entire series of observations covered less than five days, but these few observations were sufficient to determine a preliminary orbit of this object. It proved to be a minor planet with a probable diameter of less than a mile, and on Oct. 30 it approached to within 485,000 miles from the earth. Reinmuth appropriately named it Hermes.

In the summer of 1937 with the aid of the 100-inch reflector at Mount Wilson, Calif., Seth B. Nicholson discovered two new satellites of Jupiter, both extremely faint. Satellite X was 7,000,000 miles from Jupiter when it was discovered and Satellite XI was at a distance of 10,000,000 miles from Jupiter.

New and greatly improved orbital elements for the planet Neptune were derived by Lloyd Wylie, as a result of a very thorough comparison of Simon Newcomb's theory with all observations from 1795 to 1938. As a by-product of this investigation, Wylie was able to make a new determination of the mass of Pluto, which he found to be practically identical with the mass of the earth. H. L. Alden made new observations of the satellite of Neptune, Triton, and found Triton's mass to be 0.02 the mass of the earth, or 1.8 times the moon's mass.

A new calculation of the surface temperature of Venus was made by Rupert Wildt. The atmosphere of this planet was known to contain a high percentage of carbon dioxide. Laboratory measurements of the radiation emitted by gaseous carbon dioxide were used by Wildt to calculate the extent of the "greenhouse effect" which this gas could produce in the planet's atmosphere. He calculated the temperature of the subsolar point on Venus as between 93° C. and 135° C. It seemed likely, therefore, that the surface temperature of the planet might be somewhat above the terrestrial boiling point of water.

During 1944 G. P. Kuiper at the McDonald observatory made a series of spectrographic observations of the nine largest satellites in the solar system. He discovered that the largest of Saturn's satellites, Titan, has an atmosphere of methane and possibly ammonia. It seemed certain that Titan's atmosphere was probably formed after the satellite had cooled, for had the satellite ever had as high a temperature as that of the earth, any atmosphere would have escaped.

One of the fundamental yardsticks used by astronomers is the distance of the earth from the sun, frequently expressed as the solar parallax. The minor planet Eros, which comes within 16,000,000 miles of the earth at closest approach, is a good object to measure for a precise determination of the sun's parallax. A close approach had occurred in the winter of 1931, and at that time an extensive international campaign was carried out to observe the asteroid. More than 30 observatories co-operated in obtaining many thousands of observations. The results of this great cooperative effort were published in 1941 by H. Spencer Jones, who had undertaken the exacting task of reducing and analyzing the observations. The new value for the solar parallax obtained from these observations was 8".790. A by-product of the same observational material yielded a new value for the ratio of the mass of the earth to that of the moon-81.271.

The light reflected from Eros varies in a period of approximately 5 hr. 17 min. This variation had been attributed to the irregular elongated shape of the asteroid as it rotates about its shortest axis. In 1941 Franklin Roach made precise photoelectric observations of the asteroid on six nights. He found that the main features of the resulting light curve could be explained by assuming an ellipsoidal figure with dimensions in the ratio 1:4:13. Small departures of the observed light from such a theoretical curve suggested, however, that the geometrical figure of the asteroid is irregular, a conclusion previously expressed from far less accurate data.

Stars.—Detailed studies of two eclipsing stars VV Cephei and ϵ Aurigae had shown them to have exceptionally large components. The peroid of ϵ Aurigae is 27 years with an eclipse lasting nearly two years. Only one spectrum of this star was visible. G. P. Kuiper, Otto Struve and Bengt Strömgren made a very thorough study of this interesting eclipsing binary. They found that the bright star is approximately 190 times the sun's diameter and that the dark one, called an infra-red star, has a diameter 2,700

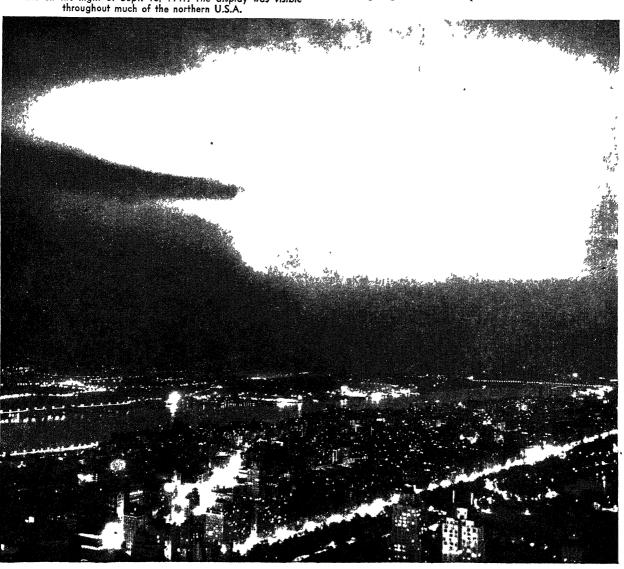

times that of the sun. The orbit is so inclined that the bright star passes behind only the outer part of the darker star. This outer part is practically transparent except for an ionized shell produced by the bright star. This ionized shell causes a weakening of the light of the bright star without greatly affecting the spectrum. VV Cephei is a similar type of binary. An extensive spectrographic study of this star by Victor Goedicke showed that the fainter red star in this case has a diameter approximately 12,000 times that of the sun. The brighter star of this pair is a hot B-type star. The faint component of ϵ Aurigae was the largest star known in 1946.

The measurement of visual double stars had sometimes been thought to be a rather unprofitable form of astronomical investigation. In 1943 K. Strand showed in spectacular fashion that this was not so. Strand had made an extensive series of photographs of the binary 61 Cygni. A thorough study of these and earlier observations clearly showed perturbations in the orbit of the visual components which were produced by a third invisible body. Strand found that he could explain these perturbations satisfactorily if he assumed that the third body had a mass of only 0.016 that of the sun (16 times the mass of Jupiter). The smallest stellar mass previously known was 0.14 the

The glitter of New York city's lights was outdone by the Aurora Borealis on the night of Sept. 18, 1941. The display was visible throughout much of the northern U.S.A.

mass of the sun. Hence this dark component of 61 Cygni must have so little luminosity, if indeed it has any, that it may be considered a planetary object. Thus, for the first time in history a planet had been discovered outside the solar system. This planet moves about one of the visible components in a period of 4.9 years. The semimajor axis of its orbit is 2.4 astronomical units but because its orbit is highly eccentric it comes within 0.7 astronomical unit of its visible companion at closest approach. Therefore 61 Cygni is a three-body system with one of its components planetary. It is 11 light years away from the earth and thus one of the sun's nearest neighbours. The visible components, red dwarf stars, revolve around their common centre of gravity in a period of 720 years. This discovery of a planetary body outside the solar system promised to alter greatly the viewpoint of astronomers concerning the possibility of the existence of other planetary systems.

Studies of eclipsing binaries had provided considerable information about the nature and physical constitution of the stars, and astronomers paid much attention to these interesting double stars during the decade 1937–46. In 1939 Gerald P. Kron obtained a highly precise light curve of the eclipsing star YZ Cassiopeiae from which he was able

Balloon clusters ready to be sent into the stratosphere. University of Chicago scientists tested for cosmic ray activities accompanying the meteoric shower visible to many U.S. observers on Oct. 9, 1946

to determine the amount of limb darkening of the brighter star. This was the most precise determination of a star's limb darkening yet made. Kron found a darkening coefficient for the large A3 star of 0.49. The theoretical value of the darkening coefficient for an A3 star was determined in 1945 by H. N. Russell as 0.51 and thus in close agreement with Kron's observed value.

The third magnitude star Beta Lyrae had long been one of the most interesting and puzzling of eclipsing binaries. Literally thousands of spectrographic and photometric observations had been made of it. During 1941, astronomers at the Yerkes observatory, Williams Bay, Wis., combined their efforts to try to explain some of the puzzling features of this eclipsing pair. Their intensive study indicated that the two stars are so close together that their atmospheres actually merge. The denser of the two, by its attraction on the particles lying between them, sets up a current of gas in their atmospheres. G. P. Kuiper found that although this gaseous stream would circulate about the stars, some of it would escape as a great spiral of gas which would form a disk of gaseous material lying in the orbit plane. Since the plane of the orbit is nearly edgewise toward observers, the gas in the spiral comes between the earth and the stars. This remarkable model of a binary system might or might not be correct. However, it was based on a thorough study of the spectra and careful dynamical calculations, and it offered an explanation for most of the puzzling features of this system. Otto Struve later found several other eclipsing pairs with characteristics similar to Beta Lyrae and for which a similar model offered the only plausible explanation then available. Apparently it should be concluded that a number of close eclipsing pairs have streams of gas associated with them.

It had long been apparent that any mechanism proposed to account for the source of stellar energy must involve a transformation of mass into energy. In 1939 Hans Bethe investigated possible transformations that could occur under conditions existing in the interiors of ordinary stars. He found that a chain reaction involving carbon as a catalyst and the transformation of hydrogen into helium would supply sufficient energy for the sun at central temperatures of 18,000,000 to 21,000,000 degrees. The central temperature would depend on the percentage of hydrogen and nitrogen available, and the values obtained by Bethe from nuclear theory agreed satisfactorily with the central temperature of the sun determined from astrophysical data. Apparently Bethe had discovered the chief source of energy for stars of the main-sequence, although this so-called carbon cycle did not explain the very rapid radiation of giant stars. A spectroscopic study of v Sagittarii by Jesse Greenstein indicated that this star's atmosphere contains a higher percentage of helium than of hydrogen. This might mean that the star has already used up much of its hydrogen and thus is well advanced in the "life history" outlined by Bethe.

In the 1920s, several investigators had suggested that the well-known Crab nebula in Taurus was probably the same object as the "guest-star" observed in the far east in A.D. 1054. Further studies of this nebula were made during

1942 by Nicholas Mayall and J. H. Oort. The observed rate of expansion indicated that it could have been produced by a stellar outburst about A.D. 1100, and the position in the sky is approximately the same as that of the "guest-star" observed in China and Japan. Since the rate of expansion of the nebular gas need not have been constant, the discrepancy in time was not serious, and these observers concluded that the "guest-star" or nova of 1054 was really a supernova. The evidence seemed conclusive that the Crab nebula was produced by this spectacular stellar outburst in the year 1054.

Galaxies.-Studies of the structure of our galaxy are complicated by the existence of clouds of obscuring matter. In 1939 Joel Stebbins and his associates reported results of precise photoelectric measures of the colours of 1332 B-type stars. These measures indicated that absorption of the obscuring clouds varies inversely as the wave length and that the strongly reddened B-stars are all found near the plane of the Milky Way in the region where no extragalactic nebulae are observed. Stebbins' results showed clearly that within the first 2,000 parsecs from the sun the absorbing material is very irregularly distributed and cannot be represented by a mean absorption coefficient. A study by W. S. Adams of interstellar spectral lines produced by these obscuring clouds indicated that they contained a high percentage of calcium and hydrogen. Lines produced by molecules of CH and CN were also found. The radial velocities of some of the clouds were found to be remarkably high. One cloud in the direction of Sagittarius was found to be receding at a velocity of 40 km/ sec. and a cloud in the direction of Cygnus showed a recessional velocity of 60 km./sec.

The direction of rotation of spiral nebulae remained difficult to determine because of the ambiguity in regard to the tilt. Edwin P. Hubble made a thorough study of this problem and was able to get rid of the ambiguity in the cases of four of these galaxies. He found that in these galaxies all of the spiral arms are trailing, and since he had established that 11 other spirals rotate in the same direction as these 4, he concluded that the spiral arms of all 15 are trailing.

A measurement of the angular velocity for the outer spiral arms of the Andromeda nebula was made by Horace Babcock. He found a constant angular velocity and an angular velocity within 10' of the nucleus of approximately zero. This seemed to indicate that a large proportion of the nebular mass is in the spiral arms rather than in the nucleus. Similar investigations of the spiral nebulae Messier 31 and 33 by A. B. Wyse and Nicholas Mayall indicated that in these nebulae the mass is likewise widely spread throughout the system, and shows very small concentration at the centre. The contrast of these results with the concentration of light near the centre of the galaxies indicated that there is no direct relation between distribution of luminosity and that of mass. Determinations of the rotation of our own galaxy were interpreted as showing high central condensation of mass. Although this might be true, the observations did not necessarily demand such an interpretation and it might be that the distribution of mass in our galaxy is more nearly similar to that found in these extragalactic spirals. Star counts in the Andromeda nebula by C. K. Seyfert and J. J. Nassau indicated that this galaxy and our own are very similar. Measures of colour in seven spirals showed the arms to be much bluer than the nucleus, and this difference in colour might be significant in explaining the contrast between high concentration of light and low concentration of mass near the centres of the galaxies.

Atatürk, Kemal

4 Ataturk (1881–1938), Turkish statesman (originally Mustafa Kemal), was born at Salonika. He became president of the national assembly in 1920 and president of the Turkish republic on Oct. 19, 1923. During his 15-year administration, he introduced a thorough westernization of Turkish social and cultural life. He was equally eminent as a military leader and as a social and political reformer; in foreign policy he showed a realistic moderation characteristic of great statesmanship. Among his own people, he achieved a wide popularity. He died at the Dolmabaghche palace in Istanbul on Nov. 10, 1938.

ATC

Atcheson, George, Jr.

Atcheson (1896—), U.S. diplomat, was born Oct. 20, 1896, in Denver, Colo. He was graduated from the University of California in 1919 with a B.A. degree. During World War I, he served in the U.S. army (1918–19) as an aeronautics instructor. Entering the diplomatic service, Atcheson was a language officer at the U.S. legation in Peking in 1920. While in Peking, he attended the College of Chinese Studies, receiving an M.A. degree in 1924. In later years, he served in consular posts in Tientsin (1928), Foochow (1928–29) and Nanking (1934), and in secretarial posts in the U.S. embassy in China.

Atcheson, who was assistant chief of the division of far eastern affairs in 1941–42, returned to the orient in late 1942 as counsellor of the U.S. embassy at Chungking. He clashed frequently with Gen. Patrick J. Hurley when the latter was U.S. ambassador, and in May 1945 Hurley had Atcheson and other members of the embassy staff removed on grounds of insubordination. Subsequently Hurley charged that Atcheson had sent a letter to the state department recommending that lend-lease aid be shipped to China's communist forces; if carried out, Hurley asserted, this move would have resulted in the downfall of Chiang Kai-shek's government. However, Sec. James Byrnes subsequently cleared Atcheson, declaring that there was no proof of "disloyalty."

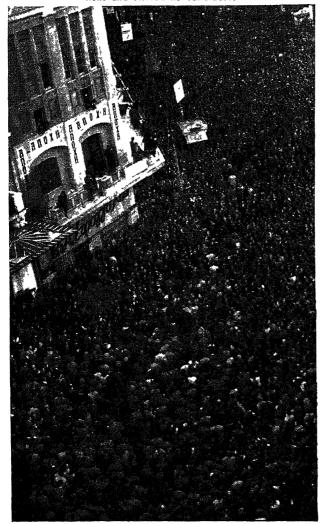

Byrnes announced on Sept. 4, 1945, that Atcheson had been appointed acting political adviser to Gen. Douglas MacArthur in Tokyo. The two worked together harmoniously and in April 1946, MacArthur named Atcheson U.S. member of the four-power Allied council for Japan. Atcheson battled continually with Lt. Gen. Kuzma Derevyanko, soviet member on the council; at the height of their disagreements, Atcheson warned May 15, 1946, that the U.S. did not favour communism "in the United States or Japan." His position was upheld by Dean Acheson, undersecretary of state. Subsequently Atcheson opposed the soviet delegate's recommendations for land reform in Japan and accused the U.S.R. of violating the Pots-

dam agreement because of its failure to repatriate any Japanese troops captured in their far eastern area.

Athens

After Germany's defeat of Greek and British troops north of the Gulf of Corinth in April, 1941, nazi forces split the country in two, entered Athens on April 27 and hoisted the swastika over the Acropolis. King George II of Greece had fled to Crete with his government several days before, and a puppet regime under General George Tsolakoglou was set up in Athens on April 30. Immediately the invaders began looting food stores and confiscating essential materials, with the result that factories closed and starvation followed. Young males were drafted into nazi labour gangs or deported, while captives from other Greek cities were marched through the streets of Athens. A wave of sabotage swept the city, and mass killings occurred frequently. So numerous were the deaths from murder and famine that there was insufficient wood for coffins to bury the dead. After more than three years of bondage, British forces landed again in Greece early in Oct. 1944, and the Germans announced on Oct. 13 that they had evacuated the capital. In December civil war flared in Athens between E.L.A.S., military arm of

E.A.M. protest rally in Athens on the eve of the Greek national elections of March 31, 1946. Leftist groups boycotted the elections and offered no candidates

the leftist E.A.M., and British-supported rightists. Street fighting between leftist guerrillas and British forces continued for several weeks, with considerable casualties among civilians, despite Prime Minister Churchill's hurried flight to Athens on Christmas day. Athens was strike bound; all gas, electricity and communications were cut off. Peace was gradually restored during Jan. 1945, and martial law ended the following month. (See GREECE.)

Athlone, 1st Earl of

The earl of Athlone (Alexander Augustus Frederick George Cambridge) (1874—), British statesman and brother of Queen Mary, was born April 14, 1874, at Kensington palace. The third son of the 1st duke of Teck, he was given the title of Prince Alexander of Teck. He was educated at Eton, and the royal military college at Sandhurst. He served in the Boer War, and was twice mentioned in dispatches during World War I. In 1917, he relinquished the styles and titles of highness and prince at the request of King George V and assumed the surname of Cambridge. That same year, he was created 1st earl of Athlone. He was governor general of the Union of South Africa, 1923–31.

Appointed 16th governor general of Canada April 3, 1940, on the death of Lord Tweedsmuir, he opened the Canadian parliament in Jan. 1944 with an appeal to all nations engaged in World War II to seek a permanent peace through world organization. On April 12, 1946, he was succeeded as governor general of Canada by Viscount Alexander of Tunis.

Atomic Bomb

The wholesale release of atomic energy, in the form of atomic bombs, was in many ways the outstanding event of the decade 1937–46. It was one of the greatest triumphs in the history of science, perhaps the most significant development in the progress of mankind after the discovery of the use of fire. It had equally vast potentialities for good and for evil. Used in another war, it would probably result in the destruction of civilization. But in its peaceful application to industry, transportation and other activities, it promised the start of a new era, the Era of Atomic Energy, capable of becoming the most glorious period in the history of mankind.

It became apparent, soon after the surrender of Japan in 1945, that the most pressing problem before the world was the control of the atomic bomb, and that no permanent solution of the international problem was possible without it. The U.S., in addition, faced the problem of evolving a domestic policy with respect to the future of atomic energy.

Based on the discovery of uranium fission by O. Hahn and F. Strassman in Germany in 1939, the atomic bomb was perfected in the U.S. during World War II as a joint venture of the U.S., British and Canadian governments. Five bombs had been detonated so far in the history of the world at the end of 1946—three in tests and two in actual warfare.

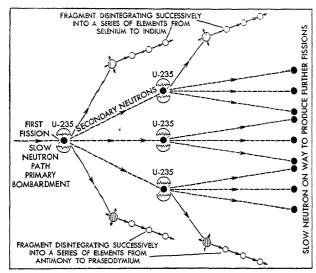

Diagram of a fission chain reaction. A slow neutron enters the uranium isotope U-235, destroying its equilibrium. The unstable isotope splits into two initial fragments, each of which decays rapidly into a whole series of radioactive and stable elements, and a considerable excess of neutrons. The fast neutrons freed by fission are slowed by moderators (not shown in diagram), strike other atoms of U-235, and the action spreads rapidly

The first bomb was exploded in a test on the New Mexico desert on July 16, 1945. Two atomic bombs were dropped on Japan from U.S. aeroplanes, the first (with more power than 20,000 tons of T.N.T.) on Hiroshima on Aug. 6, 1945 (Japanese time), the second on Nagasaki on Aug. 9, 1945 (Japanese time). Japan surrendered on Aug. 14, 1945. Former Prime Minister Winston Churchill estimated that by shortening the war, the atomic bomb had saved the lives of 1,000,000 U.S. soldiers and 250,000 British soldiers. Two more atomic bombs were exploded in tests held by joint army-navy task force 1 of the U.S. in manoeuvres known as "Operation Crossroads" at Bikini lagoon in the Marshall Islands. The first of these two bombs was detonated in the air on July 1, 1946 (Bikini time), the second was exploded under the waters of the lagoon on July 25, 1946 (Bikini time).

Science's turning point in the quest for atomic energy came in Jan. 1939, eight months before the start of World War II, with the announcement by Hahn and Strassman that barium was one of the products when uranium was bombarded with neutrons. The significance of this discovery was communicated by Lise Meitner and O. R. Frisch, refugees from Germany in Copenhagen, to Prof. Niels Bohr, who was preparing to visit the U.S. Arriving in the U.S. on Jan. 16 Bohr discussed the theory with Albert Einstein, J. A. Wheeler and others. It meant that the uranium atom had split into two nearly equal fragments, an atomic transmutation from the end of the periodic table where the binding force is least to the centre of the table where it is greatest. Calculations showed that such a "fission" of the uranium atom should release an incredible amount of energy, nearly 200,000,000 electron volts. It meant that one pound of uranium would produce by fission as much energy as the combustion of 20,000,000 lb.

Bohr and Enrico Fermi discussed uranium fission at a conference on theoretical physics in Washington, D.C., on Jan. 26, 1939, and Fermi made the further suggestion that neutrons might be released during the process. Here then was the possibility of a chain reaction of the type needed for the wholesale release of atomic energy. These sugges-

tions threw the meeting into an uproar while those physicists whose laboratories contained cyclotrons rushed to the telephone to initiate by long-distance calls experiments seeking to confirm this phenomenon of fission.

Subsequent theoretical studies by Bohr and Wheeler indicated that slow neutrons did not cause fission in ordinary uranium, or U-238, so-called because its mass number is 238, but in U-235, an isotope of mass number 235, present in ordinary samples of uranium to the extent of 1 part in 140. Gradually the many riddles presented by fission were solved and by June 1940 the basic facts concerning the release of atomic energy were known throughout the scientific world.

One important result of these studies was the discovery that with neutrons of certain speeds U-238 exhibited a high probability for neutron capture, becoming an unstable isotope, U-239, which by emitting a beta particle became a new element, No. 93, to which the name of "Neptunium" was given. But this was also unstable and by emitting another electron became element No. 94, named "Plutonium." It was also found that fission took place in both thorium and protoactinium with fast neutrons.

It was realized that the setting up of a chain reaction depended upon the number of neutrons released by the initial fissions and their subsequent fate. A neutron might escape without accomplishing any effect, it might take part in nonfission capture, or it might cause fission. The ratio of neutrons causing fission to the other neutrons is known as the multiplication factor. For a chain reaction it must be greater than one. It was also realized that the size and shape of the mass of uranium would be a factor in bringing about a chain reaction.

Physicists therefore foresaw two possibilities. One was the setting up of a chain reaction in ordinary uranium, a mixture of U-234, U-235 and U-238, employing slow neutrons for the controlled release of atomic energy for power purposes. The other was the creation of a chain reaction of explosive character in pure U-235 or plutonium with fast neutrons. This would be an atomic bomb. It was believed that the controlled reaction would require at least several tons of uranium whereas the critical size of the bomb would be between 1 and 100 kg.

A complication in obtaining the controlled reaction arose from the fact that fission releases high-speed neutrons whereas slow neutrons are the most desirable for producing fission. The suggestion was made that the uranium be mixed with some other substances of a character such that the neutrons would be slowed down by elastic collisions with its atoms. Hydrogen, deuterium, beryllium and carbon were suggested for this "moderator," as it was named. Fermi and L. Szilard proposed a superior method, namely, to embed lumps of uranium in a matrix of some moderator not unlike raisins in a cake. This construction came to be known as a "lattice" and the resulting structure as a "pile."

Construction of a bomb, therefore, required either the separation of pure U-235 from ordinary uranium or the construction of a uranium pile, not primarily for the generation of power but the transmutation of U-238 into plutonium which could then be separated by chemical means. The first sample of pure U-235 was isolated by Alfred O. Nier in Feb. 1940 by means of the mass spectrograph. Slightly larger amounts were produced shortly thereafter by K. H. Kingdon and H. C. Ollack.

Manhattan Project.—The story of the production of the atomic bomb was in many ways as unique as the bomb

Desolation of Hiroshima after the first atomic bombing of Japan on Aug. 6, 1945. An area of 4.1 sq.mi., or 60% of the city, was laid waste when the single bomb was dropped by U.S. fliers

itself. While engaged in one war in Europe and another in the Pacific, the U.S. marshalled the manpower and resources needed to complete in four years a project that otherwise might have taken half a century. The cost of the project, \$2,000,000,000, indicated its magnitude.

It was difficult to assign credit to all who took part in the venture. A brilliant group of U.S., British and refugee scientists formed its heart. But later, as the project developed and vast plants had to be built and tens of thousands of workers employed, the co-operation of a large number of the nation's chief industrial corporations as well as that of the war department and other branches of the government was required. The decision to embark on the project was made by Pres. Roosevelt himself.

The first contact with the government was made by George B. Pegram of Columbia university, who arranged a conference between Fermi and officers of the navy in March 1939. In July, L. Szilard and E. Wigner conferred with Einstein and later the three went to New York city to talk with Alexander Sachs. Supported by a letter from Einstein, Sachs explained the importance of the problem to Pres. Roosevelt, who appointed an advisory committee on uranium with L. J. Briggs, director of the national bureau of standards as chairman, to look into the problem. In Feb. 1940 a fund of \$6,000 was made available to start researches; probably no one then realized that this was the

beginning of a \$2,000,000,000 expenditure. By this time, it was well known that Hitler had embarked German physicists upon atomic bomb researches. The British were also studying the problem, and in the fall of 1941, Harold C. Urey and G. B. Pegram visited England to get first-hand information on what was being done there.

On Dec. 6, 1941, the project was put under the direction of a uranium section of the Office of Scientific Research and Development (OSRD). Members of this section were James B. Conant, representing Vannevar Bush, the director of the OSRD; L. J. Briggs, chairman; G. B. Pegram, vice-chairman; A. H. Compton, program chief; E. O. Lawrence, program chief; H. C. Urey, program chief; E. V. Murphree, chairman of the planning board; H. T. Wensel, technical aide; S. K. Allison; J. W. Beams; G. Briet; E. U. Condon; and H. D. Smyth. There was also created a "Top Policy Group," consisting of Pres. Roosevelt, Vice-Pres. Wallace, the secy. of war, the chief of staff, Bush and Conant. On June 18, 1942, the war department organized a new district in the corps of engineers to carry on the work of the atomic bomb. This was named the Manhattan District, and on Sept. 17, 1942, Brig. Gen. L. R. Groves was placed in complete charge of all army activities relating to the project. A number of British scientists were

transferred to the U.S. in 1943 and in August of that year a combined policy committee, representing the U.S., Great Britain and Canada was set up.

Because there was no way of knowing in advance what method would succeed, it was decided to work simultaneously on several methods of isolating U-235 and also on the production of plutonium.

The first experimental pile—a graphite cube about eight ft. on edge and containing about seven tons of uranium oxide—was set up at Columbia university in July 1941. At the end of the year the work on such piles was transferred to the University of Chicago, where a considerable number of related problems were being studied by a group, under the direction of A. H. Compton, in the cryptically-named "Metallurgical laboratory." On Dec. 2, 1942, the first self-sustaining chain reaction pile was put into operation, thus establishing that such a pile was feasible for the controlled release of atomic energy for power purposes or the manufacture of plutonium.

It was felt that the time had arrived when a pilot plant for the production of plutonium could be built, and it was decided to locate it on the site which had been acquired in the Tennessee valley and named the Clinton Engineer Works. This was a 70 sq.mi. tract on the Clinch river about 30 mi. from Knoxville, Tenn. A more isolated site was subsequently chosen for the full size plants, a 1,000 sq.mi. tract on the west bank of the Columbia river, north of Pasco, Wash., named the Hanford Engineer Works.

An enormous number of engineering problems had to be solved in building the Hanford uranium piles. They were so designed that the uranium was employed in the form of rods encased in metal containers. These were inserted into the piles by automatic machinery governed by remote control since no one could safely enter the chamber where a pile was located. They were subsequently removed by similar means and transported to the plants where the plutonium was separated. These likewise had to operate by remote control because of the radioactivity of the fission products in the uranium rods. Heavy concrete walls were built as shields to protect workers from the radiations released by the uranium piles and separation plants.

Meanwhile, at the end of 1941, the problem of separating U-235 from ordinary uranium had been assigned to two groups working under the direction of Urey and Lawrence. A method of separation by means of gaseous diffusion was developed by Urey and his group. This required the conversion of the uranium into a gaseous compound which was then permitted to diffuse through porous barriers. Since the rate of diffusion differs for the various isotopes, a separation was thus effected.

Lawrence and his group developed an electromagnetic method of separation which was essentially an extension of the mass spectrograph. It operated upon the principle that the amount by which a magnetic field bends the path of a stream of nuclei from a straight line depends on the weight of the nuclei. Huge plants employing both methods were built at the Clinton Engineer Works. Subsequently, in order to speed up the production of the electromagnetic plant, a thermal diffusion plant, using a method developed by P. H. Abelson, was built to make a preliminary separation of the isotopes.

For the final stages of the project, it was felt wise to establish an atomic bomb laboratory in an isolated place, both for the sake of secrecy and safety. A site was chosen at Los Alamos, N.M., on a mesa about 20 mi. from Santa Fe. J. R. Oppenheimer assumed direction of this laboratory in March 1943. A group of brilliant physicists, chem-

ists and authorities on explosives and weapons, recruited trom all parts of the U.S. and including H. Bethe, R. R. Wilson, J. W. Kennedy, C. S. Smith, Capt. W. S. Parsons, G. B. Kistiakowsky, R. F. Bacher and E. Fermi among others, moved into the laboratory. Sir James Chadwick and Niels Bohr also spent much time at Los Alamos.

By this time, researches had revealed that in a mass of either U-235 or plutonium of a certain critical size, a fast neutron chain reaction would take place in which the multiplication of neutrons would be so rapid as to bring the reaction to the point of explosive violence. The problem before the Los Alamos laboratory was to determine with great exactness this critical size and then to design a mechanism for bringing smaller masses of the material together quickly. The chain reaction would then cause the explosion. An obvious method of assembling the bomb was to load half of it into a gun and shoot it into the other half of the bomb which served as a target.

New Mexico Test.—The first atomic bomb in the history of mankind was exploded at 5:30 A.M. on July 16, 1945, at the Alamogordo air base in the desert 120 mi. southeast of Albuquerque, N.M. The bomb had been placed on a tall steel tower while scientists and military experts occupied observation posts placed at distances ranging from 10,000 to 17,000 yd. from the tower. They had been instructed to lie down with their feet toward the tower and to protect their eyes from the blinding flash of the explosion. The skies were dark and it was raining, with occasional lightning.

The explosion caused a flash that illuminated the mountain peaks 10 mi. away. Then came a tremendous, sustained roar accompanied by a tornado-like burst of wind. Where the tower had stood there was a great boiling, surging cloud of many colours rising into the stratosphere, more than 40,000 ft. in height. The heat of the explosion estimated at several millions of degrees, had completely vapourized the tower. In its place was a huge, saucershaped crater about a half mile in diameter and 25 ft. deep, the floor of which consisted of jade and turquoise coloured glass formed by the fusion of the sand.

Hiroshima and Nagasaki.—The first atomic bomb used in warfare was dropped on Hiroshima (q.v.), a Japanese army base and city of 343,000 inhabitants, at 9:15 A.M., Aug. 6 (Japanese time), 1945. The bomb was dropped from a B-29 Superfortress, the "Enola Gay." Col. Paul W. Tibbets, Jr., was the pilot and Maj. Thomas W. Ferebee the bombardier. Capt. Parsons, who had helped design the bomb, went along as the "weaponeer." The flash of the explosion was seen by a reconnaissance plane 170 mi. away. Those in the "Enola Gay" reported that a black cloud rose over Hiroshima to a height of 40,000 ft. Aerial photographs taken after the smoke and dust had cleared away showed a scene of destruction unlike any before witnessed. The entire business section at the centre of the town had disappeared except for the skeletons of three concrete buildings.

The second bomb to be used against Japan was dropped on Nagasaki at 12:01 P.M., Aug. 9 (Japanese time), from a B-29 Superfortress, the "Great Artiste," piloted by Maj. Charles W. Sweeney. It was said that the construction of this bomb was so superior that it rendered the Hiroshima model obsolete. It was first reported that the Nagasaki bomb had created a considerable crater, but later investigations showed that this report was wrong and stemmed from the existence of a crater previously caused by a bomb using T.N.T.

On June 30, 1946, the U.S. war department made public the results of the official investigation of the bombing of Hiroshima and Nagasaki. The report had been compiled by engineers and scientists of the Manhattan project who had access also to data assembled by the U.S. strategic bombing survey, the British mission to Japan and the joint atomic bomb investigating group (medical).

This report stated that Hiroshima suffered 135,000 casualties or more than half of its population. Nearly half, or 66,000, of the casualties were deaths. The greatest number of these occurred immediately after the bombing.

Nagasaki, a city of 195,000, suffered 64,000 casualties, according to this report, of which 39,000 were deaths.

The effects of the atomic bombs on human beings were of three main types, the report stated: (1) burns, including "flash" burns caused by the instantaneous heat and light radiations; (2) mechanical injuries, resulting from flying debris, falling buildings and blast effects; (3) radiation injuries caused entirely by gamma 1 ays and neutrons emitted at the instant of explosion and similar to the results of severe X-ray overexposure. The wide ground area over which burns were inflicted was particularly remarkable.

Burns caused about 60% of the deaths in Hiroshima and about 80% in Nagasaki. Falling debris and flying glass caused 30% of the deaths in Hiroshima and 14% in Nagasaki. Radiation caused 10% of the deaths in Hiroshima and 6% in Nagasaki. No harmful amounts of persistent radioactivity were found in either of the two cities.

The investigators were convinced that the destruction at both Hiroshima and Nagasaki was such as to justify the original statement that the general effect of the atomic bomb would be equivalent to an explosion of 20,000 tons of T.N.T. They also reported that the heights at which the bombs exploded were such as to have caused the maximum damage; any other bursting point for either bomb would not have been as effective. This was a tribute to the experts who had decided upon the bursting point from theoretical considerations.

In Hiroshima almost everything up to about one mile from the point on the ground directly below the burst was completely destroyed except for the buildings of reinforced concrete. In them, however, the interiors were gutted and doors, sashes, frames and all windows were ripped out. More than 60,000 of the estimated 90,000 buildings in the city were destroyed or severely damaged. In Nagasaki, reinforced concrete buildings with 10-in. walls and 6-in. floors, situated 2,000 ft. from the point on the ground below the bomb burst, collapsed. At the same distance, some 9-in. concrete walls were completely destroyed.

Philip Morrison, later professor of physics at Cornell university and one of the scientists who worked on the bomb, went to Japan at the request of the war department to visit Hiroshima and study the effect of the atomic bomb. He said that the bomb was "pre eminently the weapon of saturation," destroying so large an area so completely and so suddenly that the defense was overwhelmed. The bomb knocked out 27 of the 33 modern fire stations in Hiroshima, killing or severely injuring three-fourths of the firefighting personnel. At the same time, hundreds of fires were started. Of 298 registered physicians, only 30 escaped injury and were able to care for the survivors. Only 600 of the city's 2,400 nurses and orderlies escaped injury. Every hospital but one was badly damaged; electric power plants, railroads, telephones and telegraph lines were all put out of commission. Every citizen of Hiroshima had believed that the bomb had exploded over his own house.

Eyewitness Account.—Survivors of the bombings of the two Japanese cities told stories that would have seemed incredible and fantastic under any other circumstances. One of the most graphic came from the Rev. John A. Siemes, professor of modern philosophy in Tokyo's Catholic university. On the morning of the bombing he was sitting in his room at the Novittate of the Society of Jesus in Negatsuke, about a mile and a half from Hiroshima, halfway up the side of a broad valley. He had a view of the city from his window.

Suddenly the whole valley seemed filled with a garish light like that of a magnesium flare. At the same time, Father Siemes felt a wave of heat. A moment later there was the sound of an explosion and a blast wave which smashed his window, forcing the entire window frame out of the wall and showering him with glass. He had the feeling that a bomb had exploded directly overhead. He found every window in the building broken and his colleagues, like himself, bleeding from cuts on the hands and the face.

Rushing outdoors, they were amazed to see no bomb crater or other evidence of a nearby hit. Half a mile down the valley a group of peasant homes were on fire and the woods on the opposite side of the valley were also aflame. Father Siemes and some of the others went to the aid of the peasants whose houses were burning. They noted clouds of smoke arising over Hiroshima.

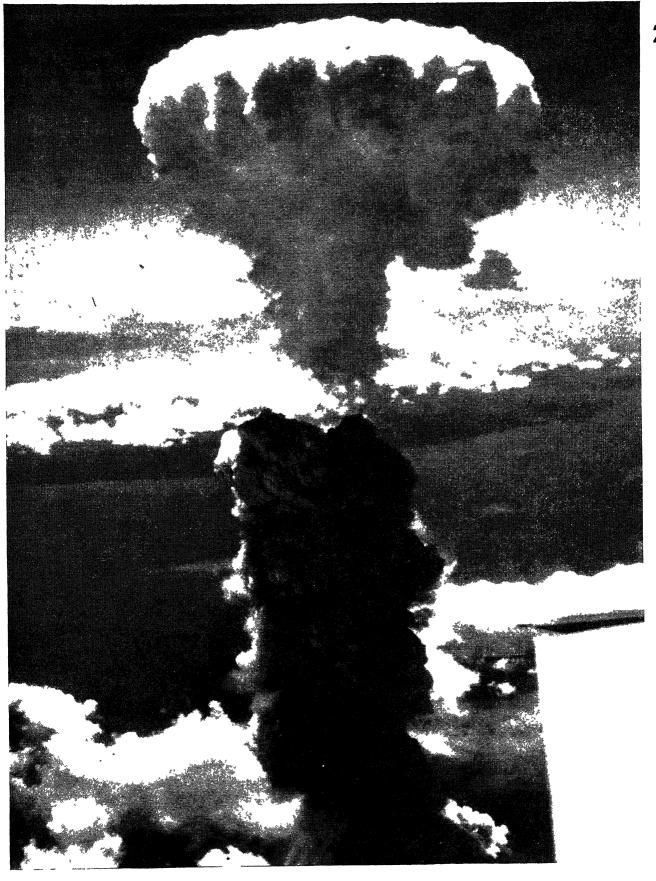

About a half-hour after the explosion, a procession of people began to stream up from the valley. The less severely injured carried or dragged the more seriously wounded. Some displayed horrible wounds of the extremities or back. There were mothers, themselves burned, carrying children with bad burns. These wounded came from the outskirts of the city. They too reported the bright light, the rush of heat, the sound of the explosion. Then, in many cases, their houses collapsed. The stream of injured grew ever greater, and by noon word came that the explosion had destroyed the entire city and that fires were raging everywhere.

Late in the day, Father Siemes and six of his colleagues went to the city on a rescue mission. The closer they got to the city, the more terrifying it appeared. The heart of Hiroshima was a gigantic burnt-out scar. They made their way along a street on the river bank among the smoking ruins and twice were forced to take refuge in the river because of smoke and flames. Everywhere they came upon the dead and the dying. Every wounded man told of relatives who had been killed. Rescue work and medical aid were virtually nonexistent in the burning city until 30 hr. after the bomb burst. (D. Dz.)

The Problem of Control

Until 1945, no individuals or groups of individuals in the U.S. were charged with the responsibility of studying the implications to society of atomic energy developments. Some thinking was done, but it was done solely on the personal initiative of a few individuals and it resulted only in the distribution of a few scattered memoranda among a limited number of Manhattan project personnel. Security regulations made difficult the exchange of ideas and viewpoints concerning the eventual repercussions of the new development, and in addition effectively prevented any study by trained economists, political scientists and sociologists.

Intimate knowledge of atomic energy developments

within the U.S. was confined, until 1945, to three main groups of persons: key military personnel of the Manhattan District, corps of engineers; industrial leaders and engineers, charged with the responsibility of designing, constructing and operating atomic bomb plants; and scientists, charged with the responsibility of conceiving, developing and improving processes for manufacturing atomic bombs.

Intimate knowledge of atomic energy developments, and for that matter even broad general knowledge of those developments, was essentially nonexistent outside those groups. The president of the U.S., the secy. of war and a few high-ranking military and naval officials knew of the developments in a broad sense. However, evidence indicated that other government departments, e.g. the state department, knew little if anything about the developments until 1945.

Thus, at the close of 1944, only six months before the first atomic bomb was exploded on the New Mexico desert, the U.S. government had no long-range plans concerning atomic energy. With the exception of the president, and possibly a few close advisers, those who were in a position to make long-range plans knew nothing about atomic energy developments. Those who were well acquainted with atomic energy were in no position to make plans, and because of the intense pressure of the work, they were in no position to make recommendations.

During the last few months of 1944 and in early 1945, with the plants at Oak Ridge, Tenn., and Hanford operating successfully, the scientists connected with the various projects were able to devote more time to considerations concerning the implications of the development.

The first major recommendation concerning U.S. policy on atomic energy, was in the form of a memorandum signed by the key scientists at the Metallurgical laboratories of the University of Chicago, and sent to the president. The memorandum, written in the early spring of 1945, recommended that immediate steps be taken to inform the American people of the new development. It was suggested that, with Germany defeated, the U.S. would not endanger itself by releasing non-technical information. It was further suggested that there would be much to be gained by having a well-informed public opinion in the U.S., at a time when the foundations for world peace were being laid.

In April Pres. Roosevelt died. Pres. Truman, as a U.S. senator, had been aware of the project, but was unfamiliar with the detailed picture. Immediately after the inauguration he was given details concerning the project by the secy. of war and Gen. Groves.

In May, Henry Stimson, the secy. of war, with the knowledge of Pres. Truman, appointed an "Interim committee" and charged it with the responsibility of formulating recommendations to the president concerning the postwar organization that should be established to direct and control the future course of the U.S. in this field. The recommendations were to cover both the research and developmental aspects of the field, and its military applications. In addition, the committee was charged with the responsibility of making recommendations with regard to the problems of both national and international control.

The Interim committee consisted of the secy. of war as chairman; James F. Byrnes, secy. of state; Ralph A. Bard, former undersecy. of the navy; William L. Clayton, assistant secy. of state; Vannevar Bush, director of the OSRD; James B. Conant, chairman of the National Defense Re-

search committee and pres. of Harvard university; Karl Compton, pres. of the Massachusetts Institute of Technology; and George L. Harrison, pres. of the New York Life Insurance company. The committee received the advice of a scientific panel consisting of physicists J. R. Oppenheimer, E. O. Lawrence, A. H. Compton and Enrico Fermi.

The Interim committee undertook an extensive investigation of the possible applications of atomic energy, and of the special problems created by the atomic bomb. A substantial fraction of the efforts of the committee was devoted to the preparation of recommendations for domestic control.

The Metallurgical laboratory at the University of Chicago was officially asked to submit its viewpoints on the social and political implications of atomic energy. Accordingly, the director of the laboratory, A. H. Compton, one of the scientific advisers to the Interim committee, appointed a committee of scientists composed of James Franck, chairman; T. R. Hogness; D. Hughes; J. Nickson; G. T. Seaborg; J. Stearns; and L. Szilard to study the matter. On June 11, 1945, that committee submitted to the secy. of war a notable report, an abbreviated summary of which follows:

The development of nuclear power not only constitutes an important addition to the technological and military power of the United States, but also creates grave political and economic problems for the future of this country.

Nuclear bombs cannot possibly remain a "secret weapon" at the exclusive disposal of this country for more than a few

Unless an effective international control of nuclear explosives is instituted, a race for nuclear armaments is certain to ensue. . . . In the war to which such an armaments race is likely to lead, the United States, with its agglomeration of population and industry in comparatively few metropolitan districts, will be at a disadvantage. . . .

We believe that these considerations make the use of nuclear bombs for an early unannounced attack against Japan inadvisable. If the United States were to be the first to release this new means of indiscriminate destruction upon mankind, she would sacrifice public support throughout the world, precipitate the race for armaments, and prejudice the possibility of reaching an international agreement on the future control of such weapons.

Much more favorable conditions for the eventual achievement of such an agreement could be created if nuclear bombs were first revealed to the world by a demonstration in an appropriately selected uninhabited area.

By the beginning of July it was believed by some of the scientists that the use of the bomb against Japan would be examined by the Interim committee primarily on the basis of expediency. With that possibility in mind, a petition was drafted by Szilard and sent directly to the president of the U.S. The petition urged the president to rule that the U.S. would not resort to the use of atomic bombs in the war unless the terms to be imposed upon Japan were made public in detail and Japan, knowing those terms, refused to surrender. The petition was signed by 67 scientists.

On Aug. 6, 1945, Hiroshima was destroyed by the new weapon. A few hours later, Pres. Truman gave the world the first official indication of U.S. policy. He stated in part:

.... We are now prepared to obliterate more rapidly and completely every productive enterprise the Japanese have above ground in any city.... Let there be no mistake; we shall completely destroy Japan's power to make war.

completely destroy Japan's power to make war...

It has never been the habit of the scientists of this country or the policy of this Government to withhold from the world

scientific knowledge. . . .

But under present circumstances it is not intended to divulge the terminal processes of production or all the military applications, pending further examination of possible methods of protecting us and the rest of the world from the danger of sudden destruction. I shall recommend that the Congress of the United States consider promptly the establishment of an appropriate commission to control the production and use of atomic power within the United States. . . .

A few days later on Aug. 10 Pres. Truman stated:

Having found the bomb, we have used it. We have used it against those who attacked us without warning at Pearl Harbor, against those who have starved and beaten and executed American prisoners of war, against those who have abandoned all pretense of obeying international laws of warfare. We have used it in order to shorten the agony of war, in order to save the lives of thousands and thousands of young Americans.

We shall continue to use it until we completely destroy Japan's power to make war. Only a Japanese surrender will

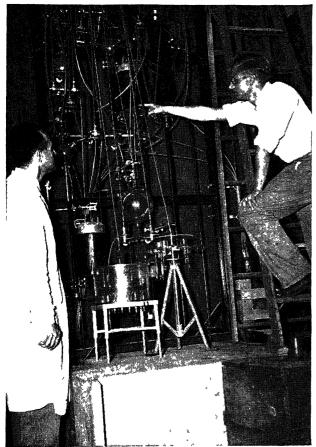

stop us.

The atomic bomb is too dangerous to be loose in a lawless world. That is why Great Britain and the United States, who have the secret of its production, do not intend to reveal the secret until means have been found to control the bomb so as to protect ourselves and the rest of the world from the danger of total destruction. . . .

Pres. Truman then made public the existence of the Interim committee under the chairmanship of the secy. of war, and he stated that Secy. of State Byrnes served on the committee as his personal representative, aiding in the preparation of plans for the future control of atomic energy.

Pres. Truman's statement precipitated considerable discussion in the U.S. and England on the question of atomic bomb secrecy. Immediately opinions were expressed in those two countries denying that secrecy could be long maintained. However, a few days later, Prime Minister

Chemical separation unit for preparing pure fission products at the Clinton laboratories, Oak Ridge, Tenn. All movement of parts and material are operated by remote control

Attlee and Winston Churchill pledged British secrecy on the bomb. In this respect at least, the policy of Great Britain supported that of the U.S.

Through Aug. and Sept. 1945 the controversy over secrecy continued. Other features of atomic warfare entered the discussions, such as questions of defense against atomic attack, and the meaning of supremacy in atomic warfare. In late September the scientists, who had been relatively silent until that time, made public statements expressing their viewpoints on the issues under discussion. The scientists stated in effect: (1) the U.S. could not expect to maintain an enduring monopoly of atomic weapons; (2) scientists could offer no hope for a specific defense against atomic bombs; (3) when other nations possessed atomic bombs, supremacy in atomic warfare would have little, if any, significance; (4) major adjustments should be made in the relationships between nations, if civilization was to survive.

Meanwhile, by the end of Sept. 1945, the Interim committee, working with the war department and the advisory panels, had prepared legislation for the control of all sources of atomic energy and activities connected with its development and use in the U.S. On Oct. 3 Pres. Truman sent a message to the senate urging the creation of legislation to establish an Atomic Energy commission, and on the same day the Interim committee proposals were introduced simultaneously in the house of representatives and senate by Rep. Andrew J. May (Democrat, Ky.) and Sen. Edwin C. Johnson (Democrat, Colo.).

May-Johnson Bill.—In his Oct. 3 message to the senate, Pres. Truman pointed out that the U.S. should proceed along two fronts of atomic energy control—the domestic and the international. He stressed that the first and most urgent step should be the determination of domestic policy, and he outlined the general features of the legislation that would be required. Concerning the international aspects, he said:

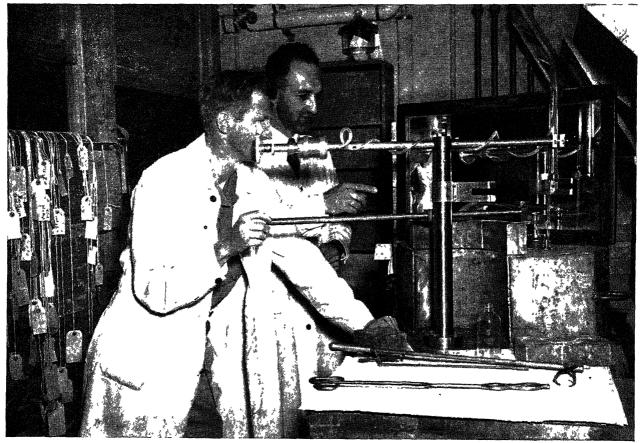

In international relations as in domestic affairs, the release of atomic energy constitutes a new force too revolutionary to consider in the framework of old ideas. We can no longer rely on the slow progress of time to develop a program of control among nations. . . .

Scientific opinion appears to be practically unanimous that the essential theoretical knowledge upon which the discovery is based is already widely known. There is also substantial agreement that foreign research can come abreast of our present theoretical knowledge in time.

The hope of civilization lies in international arrangements of the atomic bomb, and encouraging the use of atomic energy and all future scientific information toward peaceful and humanitarian ends. . . . Discussion of the international problem cannot be safely delayed until the United Nations organization is functioning and in a position adequately to deal with it.

I therefore propose to initiate discussions, first with our associates in this discovery, Great Britain and Canada, and then with other nations, in an effort to effect agreement on the conditions under which cooperation might replace rivalry in the field of atomic power. . . .

In the house of representatives, the May-Johnson bill was referred to the House Military Affairs committee. Hearings on the bill were held on Oct. 9 and, after one day, were closed. Almost immediately there arose considerable objection to the procedure that had been used, it being believed in some quarters that such an important bill should be discussed more fully before being released from the committee. As a result of those objections, hearings were reopened for an additional day on Oct. 18. After amendment by the Military Affairs committee, the bill was reported out as H.R. 4566.

Safety device for remote manipulation of radioactive material at the Oak Ridge atomic bomb plant in Tennessee. At a safe distance, and with the aid of a mirror, technicians are able to open a bottle imbedded in a heavy lead block

Considerable opposition to the May-Johnson bill developed after the hearings. Some of the more serious objections brought forth were as follows:

- 1. The bill would create a nine-man commission, all members serving on a part-time basis. Opponents of the bill believed that all commission members should serve full time.
- 2. The bill would permit all commission members to be members of the armed forces. Opponents of the bill believed that the commission should be predominantly civilian.
- 3. Opponents of the bill believed that the commission's powers as outlined were too broad. The bill delegated to the commission the authority of formulating and enforcing all national policy on atomic energy. The commission would not be responsible in the making or enforcement of policy to the president or any other authority. The commission would be virtually immune from outside criticism or review.
- 4. The commission would have full authority to issue restrictive regulations, over and above the U.S. Espionage act, on the dissemination of scientific information. In addition, the tommission could direct the dismissal of any employee of the commission, or contractor, from public or private employment, at the commission's pleasure, without regard to criminal prosecution or conviction.
- 5. The commission could manufacture atomic bombs as it alone might see fit, or it could authorize the manufacture of atomic bombs by the military or by private concerns.
 - 6. The bill contained no specific provision for the cus-

tody of atomic bombs. Either the commission or the armed forces could have sole custody.

- 7. The bill would direct the commission to conduct research for the exploitation of atomic energy for military purposes, with no reference being made to international agreement.
- 8. The bill created a full-time administrator, responsible to the commission, but delegated powers fully as broad as those of the commission. Opponents of the bill feared that the administrator might, in effect, determine the policy of the commission.

As a result of the widespread objections to the May-Johnson bill, on Oct. 29, 1945, the U.S. senate adopted a resolution establishing a Special Committee on Atomic Energy. The resolution directed the president pro tempore of the senate to appoint an 11-man committee, directed "to make a full, complete, and continuing study and investigation with respect to problems relating to the development, use, and control of atomic energy." The resolution specified that all bills and resolutions relating to atomic energy, should be referred to the special committee.

Shortly after the authorization of the Special Committee on Atomic Energy, the membership of the committee was announced: Brien McMahon (chairman), Warren R. Austin, Harry Flood Byrd, Tom Connally, Thomas C. Hart, Bourke B. Hickenlooper, Edwin C. Johnson, Eugene D. Millikin, Richard B. Russell, Millard E. Tydings and Arthur H. Vandenberg. The committee visited the atomic energy development at Oak Ridge, following which, on Nov. 27, 1945, it started extensive hearings.

Truman-Attlee-King Statement.—Meanwhile, the first official statement of combined U.S. British-Canadian policy on the international control of atomic energy was issued

on Nov. 15, 1945, after a conference between Pres. Truman, Prime Minister Clement R. Attlee of the United Kingdom and Prime Minister Mackenzie King of Canada. The three powers recommended that, at the earliest practicable date, a commission should be established under the United Nations to prepare recommendations on atomic energy. They stated that in particular the commission should make specific proposals for extending between nations the exchange of basic scientific information for peaceful ends, and proposals for establishing controls and safeguards providing for the elimination from national armaments of atomic weapons and other major weapons adaptable to mass destruction.

The Truman-Attlee-King statement officially acknowledged that no monopoly of atomic power could exist, that there was no defense against the atomic bomb and that other and more deadly atomic weapons were possible. The statement was the first acknowledgment by any of the three governments that safeguards involving inspections were essential to any successful banning of atomic bombs. The three powers emphasized that they were prepared to share, on a reciprocal basis with others of the United Nations, detailed information concerning the practical industrial application of atomic energy just as soon as effective enforceable safeguards against its use for destructive purposes could be devised.

In conclusion, the three powers stated:

Faced with the terrible realities of the application of science to destruction, every nation will realize more urgently than before the overwhelming need to maintain the rule of law among nations and to banish the scourge of war from the earth. . . . It is our firm resolve to work without reservation to achieve these ends.

Moscow Resolution.—The U.S.-British-Canadian conference in November was followed by discussions between Foreign Ministers Bevin and Molotov and Secy. of State Byrnes at the Moscow conference, held Dec. 16–26, 1945. A resolution was drawn up to be sponsored by the permanent members of the Security council plus Canada, to be introduced at the first session of the general assembly. Briefly, the resolution stated that an atomic energy commission should be established by the general assembly. The commission should be composed of one representative from each of the states represented on the Security council, and Canada. The commission should submit its reports and recommendations to the Security council.

The specific tasks of the commission were enumerated by the Moscow resolution in exactly the same language and order employed in the Truman-Attlee-King statement. It was emphasized that the work of the commission should proceed by separate stages, the successful completion of each one of which would develop the necessary confidence of the world before the next stage would be undertaken.

After the Moscow conference there was considerable discussion of the proposals, particularly in the U.S. It was feared, in some quarters, that the U.S. had committed itself to reveal some of its atomic energy information, without at the same time being provided with the necessary safeguards. On his return from Moscow, Secy. of State Byrnes stated, in a radio address delivered on Dec. 30, 1945:

The British and ourselves came to Moscow with a very definite proposal for the establishment by the United Nations of a commission on atomic energy and related matters, based on the Washington declaration of the President of the United States and the Prime Ministers of Great Britain and Canada... Our discussions were limited to this proposal. At no time did we discuss any technical or scientific matters... I was happy to find that the Soviet Government feels as we do that this particular weapon is of such a revolutionary nature that

we should explore through a United Nations commission methods of international control.

It should be understood that the task of the commission is to inquire into the problems raised by the discovery of atomic energy and related matters and to make recommendations. Neither the Security Council nor the commission has authority to bind any Government to act on its recommendations. . . .

Neither we nor any other nation would be expected to share our annament secrets until it was certain that effective safeguards had been developed to insure our mutual protection....

On Jan. 7, 1946, Secy. Byrnes issued a further statement concerning the Moscow resolution. He said that he did not see how the language used in the resolution "can possibly be construed to give the commission authority to obtain information which is not publicly available or which is not voluntarily given to it," and added that the language of the resolution made clear that the proposed commission would have authority only to make recommendations. He pointed out that unless the U.S. concurred in the recommendation, it could not be adopted. If the U.S. concurred and the Security council adopted the recommendation, it would still be for the government of the U.S. by treaty or by congressional action to determine to what extent that recommendation should be acted upon.

The United Nations general assembly, at its first meeting on Jan. 13, 1946, referred the Moscow resolution to the Security and Political committee of the assembly. The committee recommended the adoption of the resolution without changes. On Jan. 24 the assembly voted 47 to 0 to set up the 12-nation commission.

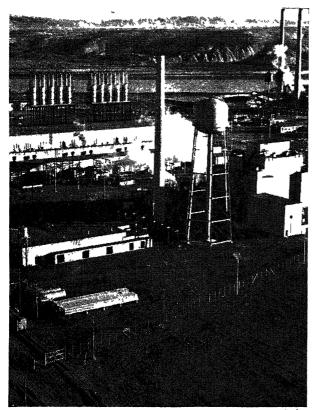

McMahon Bill.—Meanwhile, by the end of 1945, the Senate Committee on Atomic Energy had heard testimony from 22 persons including 1 economist, 1 army officer, 4 naval officers, 12 scientists and 4 industrialists. On Dec. 20, 1945, Sen. Brien McMahon (Democrat, Conn.), chairman of the committee, introduced into the senate a bill entitled the "Atomic Energy Act of 1946." The bill was referred to the committee, and during the months January—April inclusive, testimony was heard from an additional 49 individuals. After the hearings on the bill, the committee went into executive session, during which initial differences of opinion on major elements of the bill were resolved.

Perhaps the most serious debate in the senate committee occurred over the question as to whether civilians or military men should wield the most power on the proposed Atomic Energy commission. Opinions varied from the desire on the part of some for a commission dominated completely by the army and navy, to the desire on the part of others for a commission with no military representation whatsoever.

Secy. of War Robert P. Patterson expressed himself in favour of civilian control of atomic energy by endorsing a full-time, three-man civilian commission. He stated that in his opinion, the army was not competent to draw the line between basic scientific research and military techniques which should be kept secret. Secy. Patterson did, however, suggest amendments to the McMahon bill which would give the armed forces the right to conduct military research in the field of atomic power, to have the custody of atomic bombs and to be consulted on security regulations.

Gen. Groves urged, on the other hand, that the legislation provide for a part-time nine-man Atomic Energy commission containing up to four military men. He urged that a military officer on active duty be the administrator.

Considerable opposition developed to the viewpoint expressed by Gen. Groves, as well as to the less military

Richland, Wash., site of the Hanford Engineer works, one of the three U.S. atomic bomb plants erected during World War II. This picture shows a partial view of one production unit on the 450,000acre government tract

viewpoint expressed by Secy. Patterson. Considerable public debate developed, and the senate committee had difficulty in arriving at an agreement.

On March 12, 1946, the senate committee accepted by a vote of ten to one a compromise proposal of Sen. Vandenberg:

There shall be a Military Liaison Board appointed by the President composed of representatives of the Departments of War and Navy, in such a number as the President may determine. The commission shall advise and consult with the board on all atomic energy matters which the board deems to relate to the common defense and security. The board shall have full opportunity to acquaint itself with all matters before the commission.

The board shall have authority to make written recommendations to the commission from time to time as it may deem appropriate. If the board at any time concludes that any action or proposed action of the commission, or failure to act by the commission, is inimical to the common defense and security, the board may appeal such actions or proposed actions of the commission to the President, whose decisions shall be final.

Sen. Vandenberg claimed that his amendment would leave all power with the five-man civilian commission as proposed in the original bill, and would allow the military to interfere only when it might believe that the interests of national defense were threatened by action (or inaction) of the commission. Opponents of the amendment claimed that it would give the military the right and the duty to impose the military concept of security upon as wide an area of fundamental research as possible. It was believed by the opponents of the amendment that the military advisory board would attempt a continuation of the Manhattan District policy of secrecy and compartmentalization.

The fight over the Vandenberg amendment rapidly assumed the character of a major national issue. Finally, on April 2, a modified version of the Vandenberg amend-

ment was introduced and adopted unanimously by the senate committee. The changed version in effect provided for a military liaison board, but with powers greatly reduced below those provided by the original amendment.

On April 11, 1946, the revised Atomic Energy Act of 1946, changed in many respects from the original bill which had been introduced by Sen. McMahon the previous December, was reported out of committee. No action was taken by the senate until June 1, at which time the bill was passed by voice vote, almost without debate.

In the house of representatives, the bill was referred to the Military Affairs committee. On June 18 and 19, the Military Affairs committee amended the bill (1) to provide for the inclusion of two military men in the proposed five-member commission; (2) to specify that the director of the division of military application should be a member of the armed forces; and (3) to permit the army, with presidential authority, to manufacture atomic bombs.

It was quickly realized that if the amendments proposed by the Military Affairs committee remained, there would be very little chance of the revised bill passing the senate before the summer recess. In addition, public debate over the issues involved was increasing rapidly. As a result, a joint house-senate committee was given the task of resolving the differences between the two houses. The joint committee deleted the amendment providing for the inclusion of two military men in the commission, but retained the amendment requiring that the director of the division of military application be a member of the armed forces. In addition, the amendment permitting the army, with presidential authority, to manufacture atomic bombs was retained.

Finally, on Aug. 1, 1946, the Atomic Energy Act of 1946 was passed by both houses as amended. The bill was by no means completely satisfactory to all parties concerned. The provisions covering security, punishments for violations and patents were still the subjects for considerable debate even at the time of passage. However, it did give the U.S. a sufficiently concrete proposal to enable steps to be taken for the organization of controls and developmental research looking forward to the application of the new field to peaceful pursuits. (H. S. B.)

Atomic Energy Commission.—On Oct. 28, 1946, the membership of the Atomic Energy commission authorized by passage of the McMahon bill was announced. As chairman of the commission Pres. Truman appointed David E. Lilienthal, who had made a distinguished record as chairman of the Tennessee Valley authority. The other members appointed were Robert Fox Bacher, Cornell university physicist who had worked in the Los Alamos atomic bomb laboratory and later served as scientific adviser to Bernard M. Baruch, U.S. representative on the United Nations Atomic Energy commission; Sumner T. Pike of Maine, business man and former member of the Securities and Exchange commission; Lewis L. Strauss, New York banker and a rear admiral during World War II in charge of ordnance inspection; and William Wesley Waymack of Illinois, newspaper editor, Pulitzer prize winner and an economic and fiscal adviser to various government agencies in World War II.

On Nov. 4 Secy. of War Patterson and Secy. of the Navy Forrestal announced the appointment of the six-man Military Liaison committee to the Atomic Energy commission. The army membership was headed by Lieut. Gen. Lewis H. Brereton, wartime chief of the far east 9th and 10th air forces. The other army members were Maj. Gen. Lunsford E. Oliver of the army ground forces and Col. John H. Hinds, a field artilleryman who had held the wartime rank

of brigadier general. Heading the navy membership was Rear Adm. Thorvald A. Solberg, head of the research and standards branch of the shipbuilding division of the bureau of ships. He had also served as director of ship matériel at the Bikini atomic bomb tests. Other members representing the navy were Rear Adm. Ralph A. Ofstie, a naval aviator who served as aviator officer on Adm. Nimitz's staff and later commanded the U.S.S. "Essex," and Rear Adm. William S. Parsons, who had helped develop the atomic bomb, flew in the B-29 which dropped the atomic bomb on Hiroshima, and was deputy commander for technical direction at Bikini.

On Dec. 12, 1946, Pres. Truman appointed a nine-man General Advisory committee to the Atomic Energy commission, as authorized by the McMahon bill to consult with the commission on "scientific and technical matters relating to materials, production and research, and development." It consisted of James B. Conant, president of Harvard university; Lee A. du Bridge, president of the California Institute of Technology; Enrico Fermi, professor of physics in the University of Chicago; I. I. Rabi, professor of physics in Columbia university; J. R. Oppenheimer, of the University of California, wartime director of the Los Alamos laboratories of the Manhattan project; Glenn T. Seaborg, professor of chemistry in the University of California; C. S. Smith, director of the institute of metals in the University of Chicago; Hartley Rowe, vice-pres. and chief engineer of the United Fruit Co.; and Hood Worthington, chemical engineer with E. I. du Pont de Nemours and Co.

Following a series of conferences with members of the war department, the Atomic Energy commission announced on Dec. 11, 1946, that it would assume formal control of the Manhattan Engineer District—a plant valued at \$1,400,000,000, with approximately 43,000 employees.

Plans for Research.—During 1946, the Manhattan District took a number of important steps to further research in the field of atomic energy. On Aug. 2 Maj. Gen. Groves announced that Camp Upton, N.Y., had been transferred to the Manhattan District and would be made the site of an atomic research laboratory. It was later named the Brookhaven National laboratory, and Philip M. Morse, of Massachusetts Institute of Technology, was appointed its director. The contract for its operation was given to Associated Universities, Inc., a corporation formed for this purpose by Columbia, Cornell, Harvard, Johns Hopkins, Massachusetts Institute of Technology, Pennsylvania, Princeton, Rochester and Yale. It was planned to install research facilities costing \$5,000,000.

The General Electric Co., which on Sept. 1, 1946, had taken over operation of the \$347,000,000 government-owned Hanford Engineer Works, established a laboratory at that location under the direction of William D. Coolidge.

On Oct. 7, 1946, a training school in nuclear physics was opened at the Clinton laboratories at Oak Ridge, Tenn., with a class of 35 students from leading industrial and academic institutions of the nation. The plan was to give them a 12-month post-doctorate course in nuclear physics. Opportunity was provided for research in the field of designing uranium piles for peacetime applications.

Plans were also made for the construction of a \$2,500,000 uranium pile at Oak Ridge for experiments in the development of electric power through atomic energy. The contract for this pile was given to Monsanto Chemical Co., operators of the Clinton laboratories. The Manhattan District also ordered a 100,000,000-volt betatron from the General Electric Co. for use at the Clinton laboratories.

The name of the Metallurgical laboratory at the Uni-

versity of Chicago was changed to the Argonne National laboratory, and its program was expanded to include researches at a considerable number of other universities.

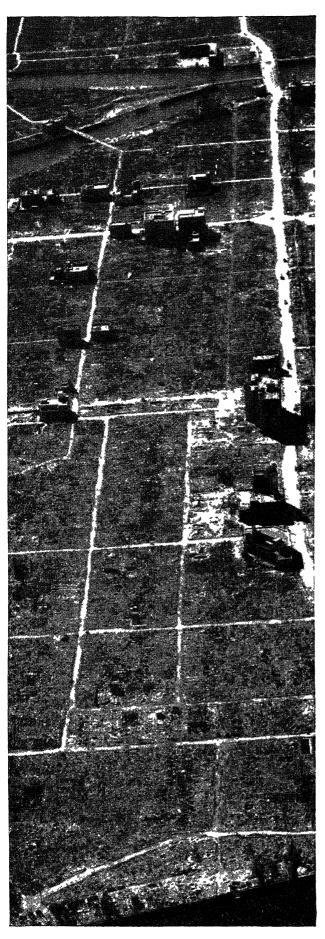

On Nov. 10, 1946, the war department announced plans for a nuclear research laboratory near Schenectady, N.Y., to cost \$20,000,000 and to be known as the Knolls Atomic Power laboratory. The contract for its design, construction and operation was awarded to the General Electric Co. Plans included the establishment of an experimental uranium pile to be used as the source of energy for an electric power plant. The Knolls laboratory was to adjoin the new General Electric laboratory at Schenectady.

One of the important problems before the nation in 1946 was the release of some of the information on atomic research in the secret files of the Manhattan District. On Nov. 7 announcement was made that nearly 500 papers, totalling about 2,000,000 words of atomic information had been cleared through the district's "declassification" procedure. It was planned eventually to publish many of these papers in a Manhattan project technical series. The declassification policy was based on recommendations of a committee headed by Richard C. Tolman, dean of the graduate school of California Institute of Technology and including R. F. Bacher, A. H. Compton, E. O. Lawrence, J. R. Oppenheimer, F. G. Spedding, and H. C. Urey. The policy was to release scientific information to further the national welfare without endangering national security.

Medical and Biological Aspects.-The medical profession had long made use of both X-rays and radium in the treatment of many diseases, including cancer. After the discovery of artificial radioactivity there was considerable research upon the use of radioactive isotopes both as a means of treating disease and as a tool for biological and medical research. Biologists had long wished for more exact information about the various metabolic processes in the living organism and the rates at which they take place. This was being obtained with the aid of radioactive isotopes which could be traced in the organism by their radioactivity. Biologists spoke of such experiments as "tracer experiments." Radioactive forms of carbon, phosphorus, sodium, potassium, iodine, iron, etc., were used in such experiments. The importance of uranium fission to the biologist and medical man arose from the fact that the fission fragments are highly unstable, undergoing many radioactive changes before they settle down into stable isotopes. The process, therefore, would put a greater volume of radiation and a greater variety of radioactive isotopes at the command of the biologist and medical man and thus lead to many advances in biology and medicine. One hope was that a radioactive isotope might be found as a specific for cancer tissue; that is, an isotope which when taken into the organism would settle only in cancer tissue.

The first delivery of radioactive isotopes to the nation's medical research institutions—pea-sized units of Carbon 14—was announced by the Manhattan District on Aug. 2, 1946. Barnard Free Skin and Cancer hospital of St. Louis received the first unit for use in cancer research. This small bit of Carbon 14 represented from 100 to 1,000 times as much of the isotope as had ever been made available previously by any single order for a cyclotron-produced isotope. Similar amounts of the isotope were subsequently furnished to a number of other institutions.

Radioactive isotopes were requested from the Manhattan District for a wide variety of researches. The subjects

included the mechanism by which cancer is produced, mechanisms by which plants utilize sunlight and carbon dioxide, disfunction of the thyroid glands, growth and composition of teeth and bones, utilization of sugar in diabetes, utilization of all essential food components, turnover of iron in anaemic conditions, absorption by plants of essential elements from the soil, vulcanization and polymerization of rubber and problems associated with radioactive isotopes themselves.

The U.S. public health service joined the program of the Clinton laboratories at Oak Ridge on Nov. 5, 1946, with the announcement of the formation of a new division in the National Institute of Health. Alexander Hollaender, principal biophysicist of the institute, was assigned to Oak Ridge to direct a research into the effect of nuclear radiation upon living cells. The work was divided into five general fields—biochemistry, cytogenetics, general physiology, experimental radiology and co-operative studies.

International Problem

In his message to congress on Oct. 3, 1945, Pres. Truman had called attention to the necessity of international action in the field of atomic energy and declared his intention of conferring with the British and Canadian governments. Prime Minister Attlee arrived in Washington, D.C., on Nov. 11, 1945, for a conference with Pres. Truman and Prime Minister Mackenzie King.

In a joint statement on Nov. 15, the three heads of government expressed their willingness to share, on a reciprocal basis with other members of the United Nations, the practical applications of atomic energy "just as soon as effective safeguards against its use for destructive purposes can be devised." (See "Truman-Attlee-King statement," above.)

Diplomats eagerly awaited the soviet reaction to the Truman-Attlee-King statement. The U.S. Daily Worker, which had often reflected accurately official Moscow opinion, called the agreement a blackjack with which the U.S. and Great Britain sought to bludgeon the U.S.S.R. into their way of thinking on international issues. Secy. of State Byrnes denied any such attempt upon the part of the U.S. in an address in Charleston, S.C., on Nov. 16.

The atmosphere was cleared for the time being by the issuance on Dec. 27 of the text of an agreement reached by the foreign ministers of the U.S., Great Britain and soviet Russia meeting in Moscow. This agreement contained, along with other matters, a resolution (see above) to be proposed to the general assembly of the United Nations for the creation of an Atomic Energy commission to deal with the four points set forth in the Truman-Attlee-King agreement.

On Jan. 24, 1946, the general assembly of the United Nations, meeting in London, unanimously adopted the resolution proposed by the foreign ministers at Moscow for the creation of an Atomic Energy commission. Secy. of State Byrnes hailed the event as a means of avoiding an international armaments race. Its immediate adoption had been urged by Andrei Y. Vishinsky, the soviet deputy foreign commissar.

Twelve nations were accorded representation on the Atomic Energy commission. They were the U.S., U.S.S.R., Great Britain, France, China, Canada, Australia, Poland, the Netherlands, Mexico, Egypt and Brazil. Some of these nations delayed appointing their representatives to

Aerial view of Hiroshima after it had been levelled by a single atomic bomb in Aug. 1945. This section was once a congested area of factories and houses the commission in the succeeding months and on April 6, Trygve Lie, secretary general of the United Nations, issued a statement pointing out the urgency of the situation and urging the nations to hurry with their appointments.

Acheson-Lilienthal Report.—On March 28, 1946, the U.S. state department made public its "Report on the International Control of Atomic Energy," known also as the Acheson-Lilienthal or the Lilienthal report. It was drawn up for the state department's committee on atomic energy, of which Dean Acheson, undersecretary of state, was chairman, by a board of consultants headed by David E. Lilienthal who, at the time, was chairman of the Tennessee Valley authority.

The members of the Lilienthal's board of consultants were J. Robert Oppenheimer; Charles Allen Thomas, vice-pres. and technical director of the Monsanto Chemical Co.; Harry A. Winne, vice-pres. in charge of engineering of the General Electric Co.; and Chester L. Barnard, pres. of the New Jersey Bell Telephone Co. Members of Acheson's committee were Vannevar Bush, James B. Conant, Maj. Gen. Leslie R. Groves and John J. McCloy, former assistant secy. of war.

One of the chief elements of every discussion of the atomic bomb on the floor of congress and elsewhere had been the question of secrecy. This was dealt with in the letter of transmittal accompanying the report, which made it clear that there would be no immediate disclosure of the nation's secret information, but that disclosures would be progressive and would keep pace with the development of the international situation.

Several stages were contemplated in the release of secret information. The first would be the release of only such information as was necessary to make clear the proposals on which world agreements could be based. The letter stated, "We estimate the degree of its importance and the effect of its disclosure to be as follows: If made known to a nation otherwise equipped by industrial development, scientific resources and possessing the necessary raw materials to develop atomic armament within five years, such disclosure might shorten that period by as much as a year."

The Acheson-Lilienthal report began with recognition of the fact that the atomic bomb had given mankind "means of destruction hitherto unknown" and that the U.S. public had reacted with expressions of horror and concern to the thought of a war fought with atomic weapons. It pointed out next that it was generally recognized that there could be no adequate military defense against atomic weapons. It further stated that there could be no lasting monopoly in atomic weapons and emphasized the fact that an atomic bomb possessed its greatest advantage as an aggressive weapon of surprise.

The report took the stand that any mere agreement to outlaw the atomic bomb was insufficient and unworkable, largely because of the fact that the development of atomic energy for peaceful purposes and the development of atomic energy for bombs were, in much of their courses, interchangeable and interdependent. Thus the only assurance that atomic plants would not be converted to destructive purposes would be the pledged word and good faith of each nation involved. This fact put an enormous pressure upon national good faith and created suspicion on the part of other nations that their neighbours' pledged word would not be kept. This danger was accentuated by the fact that the atomic bomb's greatest effectiveness lay in its use as a surprise weapon; fear of such a surprise violation of pledged word would surely break down any confidence in a mere agreement or treaty.

For this reason, the report concluded, there was no prospect of security against atomic warfare in a system of international agreements to outlaw such weapons, even though the agreement was implemented by inspection and similar police-like methods.

At the heart of the plan for the control of atomic energy proposed by the Acheson-Lilienthal report was the so-called denaturing process discovered in 1943 but never disclosed until the publication of the report. Even so, the report gave no technical details of the process, describing it only in the broadest general terms.

It appeared that both uranium 235 and plutonium could be "denatured;" that is, they could be mixed with some substance which has the effect of slowing down the rate at which nuclear fission can take place in these substances. As a result they can be used for the release of nuclear energy for industrial or experimental purposes but not for the manufacture of a bomb, for the bomb depends upon a lightning-like chain reaction in which the process of nuclear fission takes place in the entire mass of material in about one ten-millionth of a second.

The denaturants, the report stated, are so difficult to remove that plants comparable to the one at Oak Ridge would have to be built by any nation which sought to purify denatured uranium or plutonium in order to construct a bomb.

Making use of this possibility of denaturing fissionable materials, the report sought to set up a plan whereby every nation could develop the use of atomic energy to the fullest for peacetime purposes while at the same time it would be impossible for any nation to produce an atomic bomb. To accomplish this, it proposed the creation of an international Atomic Development authority or ADA.

Every nation would turn over to this ADA the ownership of its uranium deposits. Only the ADA would be permitted to mine uranium or related substances and to purify them. All plants and factories operated by the ADA would be under the jurisdiction of the United Nations and not the nation in which they were located. All uranium 235 and plutonium manufactured at these plants would be immediately denatured, and the denatured material would then be made available to the nations of the world for any peaceable purpose that they saw fit.

The plants for the separation of the fissionable materials and their subsequent denaturing would be distributed strategically throughout the world so that no one nation would contain an undue proportion. Should any nation seize an ADA plant for warlike purposes, it would be at the disadvantage of knowing that the rest of the world could immediately convert the other plants to the production of bombs. The fact that it was thus in a weak position, with the rest of the world arrayed against it, would deter any nation from such action.

It was apparent that the plan was based upon the premise that atomic energy could be brought under control by controlling uranium. Obviously the whole situation would be enormously complicated if, e.g., some scientist discovered a method of releasing atomic energy from some common substance like clay or iron. The report made it plain that no such discovery was anticipated in the near future.

The report, however, advocated that thorium as well as uranium be placed under the jurisdiction of the ADA, since thorium undergoes nuclear fission like uranium. A chain reaction cannot be maintained in thorium alone, but it can be in a mixture of uranium and thorium. By

the use of such a mixture, thorium can be converted into a dangerous fissionable material just as ordinary uranium can be converted into plutonium. Hence it was felt imperative to bring thorium as well as uranium under the control of the ADA; other chemical elements would be added to the control list only if future scientific and technical developments rendered such control advisable.

The strength of the plan proposed by the Acheson-Lilienthal report lay in the fact that it recognized the clear necessity of developing the peacetime uses of atomic energy. The report pointed out that if no attempt was made beyond outlawing the bomb and setting up an inspection system to hunt for bombs, it would be obviously difficult to recruit international enforcement officers. Such a plan might "draw the kind of men who were attracted to prohibition squads in years past."

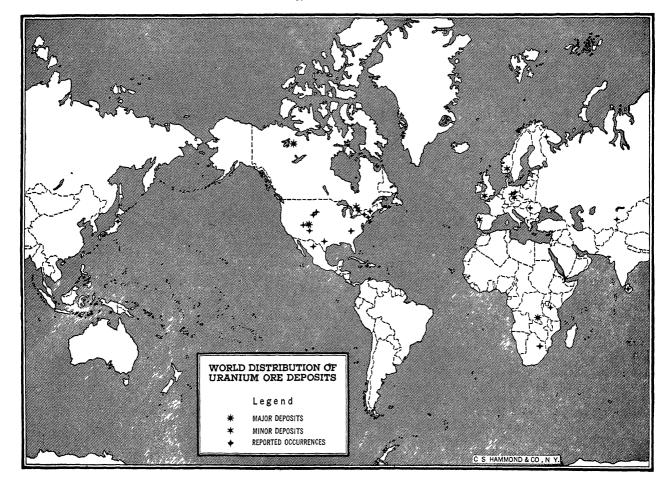

The two great fields of development envisioned by the report were the use of atomic energy as a controlled source of industrial power and the application of nuclear processes to research in medicine, biology and related fields. The plan divided all activities involving atomic energy into two categories—"safe" and "dangerous." All "dangerous" activities would be placed in the hands of the ADA. Each nation would be left free to do exactly as it pleased in the realm of "safe" activities; any activity would be regarded as dangerous if it could contribute to the manufacture of an atomic bomb.

The ADA would be truly international in character and would be set up as one of the subsidiary agencies of the United Nations, designed to be more than a body of police and detectives in the field of atomic energy. Its purpose would be dual: maintenance of world security and the prevention of the manufacture of atomic bombs, and promotion of the beneficial use of atomic energy.

The first activity of the ADA would be to bring under its control the world's entire useful sources of uranium and thorium. But it would also conduct continuous surveys for new deposits so that it would have the most complete knowledge of the world geology of these materials. In addition, it would constantly explore new methods for recovering these materials from ores in which they occurred in small quantities. The allocation of these positive duties to the ADA would, it was believed, attract geologists, engineers, physicists and chemists to it when these scientists might regard the sole duty of inspection as irksome and unattractive.

The second major function of the ADA would be the operation of all plants for the separation of uranium and thorium, the production of Uranium 235 and plutonium and the subsequent denaturing of these materials. Thus, the ADA would take over the operation of the U.S. plants at Oak Ridge and at Pasco, Wash. But as in the case of the mining operations, the ADA would be charged with the development of new and improved production methods, thus again attracting to itself many of the world's leading scientists and engineers. The ADA would even have to carry on continuous researches on atomic bombs since its function of preventing the production of bombs would require it to be the world's best-informed body on the production of such bombs.

The Baruch Proposal.—Bernard M. Baruch, America's "elder statesman," was appointed U.S. representative to the United Nations Atomic Energy commission on March 18, 1946, ten days before issuance of the Acheson-Lilien-

thal report. Baruch immediately announced the appointment of a team of "alternates and co-workers" consisting of John Hancock, Ferdinand Eberstadt, Herbert Bayard Swope and Fred Searls. He also said that he would seek the guidance of Vannevar Bush, James B. Conant, Arthur H. Compton and Maj. Gen. Groves. Because of delays in the appointment of the delegates of some nations, the United Nations Atomic Energy commission was not ready to meet until June.

On June 14, 1946, Baruch presented the "United States Atomic Energy Proposals" to the commission. These closely paralleled the Acheson-Lilienthal report but differed in some respects. They were elaborated in three official memoranda presented later to the commission, "The Control and Development of Atomic Energy" on July 2, "The Functions and Powers of the Atomic Development Authority" on July 5 and "The Relation of the ADA to Other Organs of the United Nations" on July 12.

These memoranda proposed the creation of an international Atomic Development authority to control the production and use of uranium and thorium, all fissionable materials and their products. Free access for international inspection was stipulated. There were provisions for specific punishment for illegal possession or use of atomic bombs or materials from which bombs could be made or for seizure of property belonging to the ADA or for other willful interference with activities of the ADA.

An important feature of the Baruch proposals was that no nation could be protected from punishment for violation of the proposed international control treaty through the use of the veto whether this veto was cast by the violating nation or any other nation possessing the veto power.

Andrei A. Gromyko, representative of the soviet union on the United Nations Atomic Energy commission, presented a soviet counterproposal to the commission on June 19. He stated that the continued production of atomic bombs in the U.S. was serving to intensify mistrust between nations. He proposed an international agreement to outlaw the production of atomic bombs and to provide for the destruction of all existing stocks of bombs within three months. It seemed clear that the soviet union was resisting the idea of international inspection.

The Baruch proposal was supported in principle, however, by the delegates of Australia, Brazil, Canada, China, Egypt, France and the Netherlands. Great Britain and Mexico also went along to a lesser degree. The representative of Poland urged immediate steps to outlaw the atomic bomb as proposed by the soviet delegate.

It was immediately clear that a wide gulf separated the official views of the U.S. and soviet Russia. The U.S.S.R. wanted the U.S. to stop making bombs immediately. It apparently believed that a treaty under which all nations agreed not to make bombs was sufficient to control the situation. It proposed that the treaty contain provisions for national legislation in each state for the punishment of violations of the treaty. Soviet Russia resisted any interference with its veto power, but proposed a committee of the United Nations for the exchange of scientific information and joint scientific programs for the use of atomic energy in the public welfare of all peoples.

The U.S. view, as originally set forth in the Acheson-Lilienthal report, was that a mere treaty was insufficient. An international inspection service was demanded. To this Baruch added the provisions for penalties for violation of the agreement or interference with the ADA. He also insisted that no veto apply under the ADA.

The difference of opinion was so wide that many observers feared that it might split the entire United Nations

organization. Both the U.S. and the U.S.S.R. appeared willing to negotiate but only on the basis of its own plan. As 1946 drew to a close, however, it seemed as though the tension was beginning to decrease.

The situation looked brighter in Dec. 1946 when Molotov indicated that the U.S.S.R. might decide to agree to a system of international inspection, and when the U.S.S.R made proposals on disarmament in general which the U.S. delegate to the United Nations general assembly indicated would be acceptable to the U.S. if they also were extended to include the principle of inspection.

The Bikini Tests

The U.S. navy suggested on Sept. 16, 1945, that the captured Japanese battleship, "Nagato," be used to test the effect of an atomic bomb upon a battleship. It was recalled that on July 18, 1921, a squadron of army planes under Brig. Gen. William L. (Billy) Mitchell sank the former German cruiser "Frankfurt" off the coast of Virginia, and two days later sank the former German dreadnought, "Ostfriedland." On Sept. 5, 1923, army bombers under Mitchell's direction sank the obsolete U.S. battleships, "New Jersey" and "Virginia," off Cape Hatteras.

The navy suggestion set in motion a train of events that culminated in the summer of 1946 in the atomic bomb tests at Bikini atoll in the Pacific. Soon after the navy announcement the army air forces demanded a share in the tests, and as a result it was decided on Dec. 10 to make the event a joint venture of the war and navy departments. The joint chiefs of staff created joint armynavy task force 1 and appointed Vice-Adm. William H. P. Blandy as its commander. The name "Operation Crossroads" was chosen for the tests, as Adm. Blandy told the senate special committee on atomic energy, because of its "possible significance." It was realized that seapower and airpower, perhaps civilization itself, were at the crossroads. Blandy revealed that his staff included Maj. Gen. W. E. Kepner as deputy commander for aviation; Rear Adm. W. S. Parsons, deputy commander for technical direction; Maj. Gen. Anthony C. Auliffe, army ground forces adviser; R. A. Sawyer of the Manhattan District, technical director; and Capt. J. A. Snackenberg, U.S. navy, chief of staff. Bikini atoll had been chosen as the site of the tests and three tests were contemplated. In the first, scheduled for early in May 1946, a bomb would be dropped over a target fleet from a B-29 Superfortress. In the second, scheduled for July, a bomb would be exploded just under the surface of the water. In the third, scheduled for 1947, but cancelled by Pres. Truman on Sept. 7, 1946, it was planned to explode a bomb in deep water. Admiral Blandy said that it was planned to use a large number of target ships, including battleships, aeroplane carriers, cruisers, destroyers and submarines.

Located in the Marshall Islands in the Pacific, six degrees north of the equator, the Bikini atoll was known prior to World War II as the Eschholtz atoll. It is 70 mi. east of the island of Eniwetok and about the same distance northwest of Kwajalein, an important army air force and navy base in World War II. The atoll is a coral ring of more than 20 islands, of which the principal is Bikini Island, 21½ mi. long. The lagoon inside the atoll is 20 mi. long and 12 mi. wide. Plans for Operation Crossroads made it necessary to evacuate the natives from Bikini Island, and accordingly "King" Juda and his 165 followers were moved by seaplane to Eniwetok.

A storm of objections to the test arose from many

quarters. Many authorities thought the tests ill-timed. Rep. R. Thomason (Democrat, Tex.), senior member of the military affairs committee, said, "In less than 10 months after V-E day, with all the war talk that is going on, you are sending these ships out to the far Pacific for a vast display when the world is on fire and everybody thinks we are going to have another war with a great power."

Another objection was to the cost. Congressmen pointed out that they were being asked to permit the use of ships which originally cost \$400,000,000 as targets in the tests.

The Federation of Atomic Scientists apposed the tests. In a letter to the *Review of Scientific Instruments*, L. A. du Bridge declared, "It is safe to dismiss as negligible the scientific value of the tests."

There were rumours of friction over the tests between the navy and the army air forces, and on March 1, 1946, Blandy made a statement that there was "no desire to rig this test" either for or against the navy or the army air force.

Meanwhile, Sen. McMahon proposed to Pres. Truman that final control of the tests and their evaluation be placed in the hands of a board of civilians and not in the armed forces. Eventually two evaluation boards were created, one known as the Evaluation Board of the Chiefs of Staff, the other as the President's Evaluation board.

Finally, there was a flood of complaints and dire predictions from ill-informed persons who prophesied destruction of all the fish in the sea, tidal waves, earthquakes and the splitting open of the floor of the Pacific, with all the water disappearing into the earth's interior.

Adm. Blandy made it clear that there was no intention of any attempt to simulate battle conditions in the test. The chief purpose of the test was "to provide the data which are needed by the Army and Navy in planning for the future along sound and economical lines." A secondary purpose was "to provide the data which scientists desire" insofar as this did not conflict with the primary purpose.

On March 23, 1946, when preparations for the Bikini tests were well advanced with a large part of joint task force 1 at work at Bikini, Pres. Truman announced, without warning, that the first bomb explosion, then set for May 15, would be delayed about six weeks. The White House announced that this was done to enable congress to keep at work on the legislative program since a large number of senators and representatives wished to see the test. There was much speculation as to whether or not international considerations were behind the president's decision. Blandy stated that the delay would throw the bomb tests into a period when weather conditions might prove more difficult.

The magnitude of Operation Crossroads was exemplified by the fact that joint army-navy task force 1 included 150 ships and a personnel of 40,000 men. Seventy-six aeroplanes were included in the force. The U.S. invited each of the nations represented on the United Nations Atomic Energy commission to send official observers and press representatives to the test. The official observers travelled to Bikini on the U.S.S. "Panamint" and the press representatives, along with the U.S. news correspondents and radio commentators, on the U.S.S. "Appalachian."

The Target Ships.—Seventy-five ships were placed in the target area for the first test. The battleship "Nevada," at the centre of the target area, had been painted with bright orange and white stripes as an aid to the bombardier who was to drop the atomic bomb. The "Nevada" was approximately three miles from the white sands of the palm-fringed beach of Bikini Island.

Four other battleships and two aeroplane carriers were placed close to the "Nevada." These included the "Pennsylvania," which like the "Nevada" had survived the Japanese attack on Pearl Harbor, the "Arkansas," which first saw action at Vera Cruz in 1914, the "New York," likewise a veteran of World War I, the captured Japanese battleship "Nagato" and two aircraft carriers, the "Saratoga," veteran of World War II campaigns in the Pacific, and the smaller "Independence." These seven ships were tied up to mooring buoys close together. The usual method of anchoring ships so that they can swing at anchor without danger of collision was not followed.

The other ships were arranged around these seven in an area with a radius of approximately 1,000 yd. They included battleships, cruisers, destroyers, attack transports, submarines and various smaller craft. Among them were two of the oldest and heaviest U.S. cruisers, the "Pensacola" and the "Salt Lake City" and the German heavy cruiser, "Prinz Eugen," which did much damage in the early days of World War II. The arrangement bore no relation to the usual method of deploying a task force under battle conditions. For example, a line of destroyers extended outward from the inner portion of the target area. This was so that the effect of the bomb might be determined on comparable ships over increasing distances.

Devices ranging from complex scientific apparatus whose exact nature was a scientific secret to empty gasoline cans were included in the scientific instruments distributed on the 75 target ships and the shore of Bikini Island. An empty gasoline can makes a good pressure recorder because it is easy to determine in advance how much force is needed to cave in its sides.

The ships themselves constituted scientific instruments since a ship is a complex structure about which a great deal is known, and naval engineers and architects would be able to interpret what happened to the ships in the test.

The apparatus distributed throughout the target areas included pressure recorders, temperature recorders and apparatus to measure the radiations from the bomb. These were supplemented with live animals including goats, pigs and rats. All sorts of equipment ranging from aeroplanes to samples of paint were exposed on the decks of the target ships. Still and motion picture cameras, controlled by automatic devices, were installed on towers on Bikini Island.

A spectacular feature of the plans for Operation Crossroads was the use of drone planes and boats. It was planned to fly pilotless planes or "drones" closer to the atomic cloud than a pilot could safely fly. These planes would be headed into the danger area by control planes and "picked up" again on the other side of the danger area by other control planes. Plans were also made to use drone boats, controlled from aeroplanes, to take samples of the water in the lagoon immediately after the bomb explosion.

Test Able.—The first bomb test at Bikini, on July 1 (Bikini time) was usually spoken of as "Able"—code word for the letter "A." The ships of task force 1 stood off to sea, approximately 20 mi. north of Bikini for the test. At exactly 30 sec. after 9 A.M., the atomic bomb was dropped from the B-29, "Dave's Dream." Col. Woodrow P. Swancutt was the pilot and Maj. Harold H. Wood the bombardier.

Observers with the task force saw a bright lightning-like flash when the bomb exploded. A ball of fire appeared on the horizon in the direction of Bikini Island; it grew rapidly until it appeared three miles in diameter. Then it collapsed as quickly and in its place was seen the atomic bomb cloud climbing into the sky. It rose to a height of five miles in about two and a half minutes, luminous, creamy white in colour, marked with streaks of pink, old rose, apricot, salmon and other pastel colours. The top of the cloud quickly fanned out into the familiar "mushroom." Ten minutes after the bomb explosion, black smoke began to rise on the horizon, indicating that the bomb had set a number of ships on fire.

By noon of July 1 the radioactivity had subsided sufficiently to permit the ships of task force 1 to re-enter the lagoon. The press and radio representatives made a tour of the target area in an LCT on July 2 and boarded several of the damaged ships on July 3 and 4.

On July 11, reports of the two evaluation boards were made public. The members of the Evaluation Board of the Joint Chiefs of Staff were Karl T. Compton, chairman; Bardley Dewey, deputy chairman; Thomas F. Farrell; Gen. Joseph W. Stilwell; Lieut. Gen. Lewis H. Brereton; Rear Adm. W. R. Purnell; and Rear Adm. R. A. Ofstie. Their report can be summarized as follows:

When the bomb exploded, a destroyer and two transports sank promptly and another destroyer capsized and sank later; the Japanese cruiser "Sakawa" sank the following day. The superstructure of the submarine "Skate" was badly damaged. The light carrier "Independence" was badly wrecked by the explosion and gutted by fire. All of these vessels were within one-half mile of the explosion point. Numerous fires were started on other ships, including one two miles distant, which was apparently the result of some unusual circumstance since all the other fires were much closer. The only major combatant ships within a half mile of the explosion point were the battleships "Nevada" and "Arkansas" and the

Operation Crossroads, showing the cloud formation above a 1/2-mi. wide column of water following the first underwater detonation of an atomic bomb, near a fleet of target ships anchored off Bikini atoll in the Pacific on July 25, 1946. This photo was taken by an automatic camera from the atoll

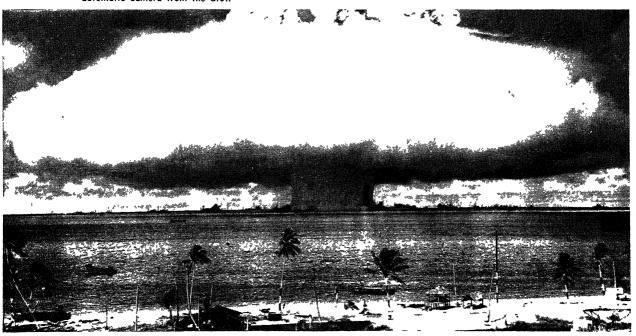

heavy cruiser "Pensacola." The superstructures of these were badly wrecked and they were unquestionably put out of action and would, along with many others within three-fourths of a mile, have required extensive repairs at a principal naval base. Other ships suffered varying degrees of damage, but there was relatively little damage at distances greater than three-fourths of a mile.

Examination of the flashburn effects produced by the initial radiation from the explosion indicated that casualties would have been high among exposed personnel, but persons sheltered within the hull of a ship or on deck in a shadow would not have been immediately incapacitated by burns alone. However, persons within the area of extensive blast damage to ship superstructures, even though within the ships, would have been exposed to a lethal dosage of radiological effects.

Essentially the same conclusions were given in the report of the President's Evaluation board. The members of this board were Sen. Carl A. Hatch (Democrat, N.M.); chairman, Sen. Leverett Saltonstall (Republican, Mass.); Rep. Walter G. Andrews (Democrat, N.Y.); Edward U. Condon; Karl T. Compton; Bradley Dewey; William S. Newell; and Fred Searls.

In a subsequent report made public on Aug. 2, the Evaluation Board of the Chiefs of Staff stated that the bomb had burst so that only one ship was within 1,000 ft. of the surface point directly underneath, that there were about 20 ships within half a mile, all badly damaged, many being put out of action, and five sunk. It added that measurement of radiation intensity and study of the exposed animals showed that the initial flash of principal lethal radiations would have killed almost all personnel normally stationed aboard the ships centred around the air burst and many others at greater distances.

Test Baker.—The second test at Bikini, frequently referred to as "Test Baker" (for "B"), took place at 8:35 A.M. on July 25 (Bikini time). The bomb was exploded "well below" the surface of the lagoon. It had been suspended from LSM-60 near the centre of the target array.

At the moment of explosion, a luminous dome rose on the surface of the lagoon, followed by an opaque cloud that enveloped about half of the target area. The cloud disappeared in two seconds, revealing a column of ascending water which lifted the 26,000-ton battleship "Arkansas" into the air for a brief moment. The column of water, about 2,200 ft. in diameter, rose to a height of 5,500 ft., sending spray still higher. It was estimated that the column contained 10,000,000 tons of water.

The column held its shape for several minutes while an expanding column of spray from it engulfed about half of the target ships. The base of the column was surrounded by a wall of water several hundred feet high, while waves going outward from the explosion were from 30 to 100 ft. high even at a distance of 1,000 ft. However, the waves diminished rapidly and were only seven feet high at Bikini Island, about three miles from the explosion point.

The Evaluation Board of the Joint Chiefs of Staff reported that two major ships sank, the battleship "Arkansas" immediately, and the heavy-hulled aircraft carrier, "Saratoga," seven and a half hours later. A landing ship, a landing craft and an oiler also sank immediately while the destroyer "Hughes," in sinking condition and the transport "Falcon," badly listing, were later beached. The submerged submarine "Apogon" went to the bottom, and one to three other submarines were believed to have sunk. The badly damaged Japanese battleship "Nagato" sank five days later.

The board reported that the explosion produced intense radioactivity in the waters of the lagoon. The radioactivity immediately after the burst was estimated to have been the equivalent of many hundreds of tons of radium; exposure to it would have incapacitated personnel and caused death within a few days or weeks. The target ships were showered with radioactive water so lethal that four days after the test it was still unsafe for inspection parties to spend "any useful length of time" in the centre of the target area or on the ships anchored there.

The President's Evaluation board devoted part of its second report to a comparison of the two tests. After calling attention to the fact that both bombs sank some ships, it concluded that the ships remaining afloat appeared to suffer more damage from the aerial explosion, but that the effects of persistent radioactivity on personnel would have been much greater in the second.

The report concluded: "As was demonstrated by the terrible havoc wrought at Hiroshima and Nagasaki, the Bikini tests strongly indicate that future wars employing atomic bombs may well destroy nations and change present standards of civilization. To us who have witnessed the devastating effects of these tests, it is evident that if there is to be any security or safety in the world, war must be eliminated as a means of settling differences among nations."

Future of Atomic Energy

Scientists agreed with Adm. Blandy that Operation Crossroads was well named. One of the roads led to an international atomic armament race certain to end in World War III and the destruction of civilization. The other road led to the peaceful development of atomic energy for the good of all humanity. They felt that the U.S. had started in the right direction by placing atomic energy under the control of a civilian Atomic Energy commission. But they realized that the fate of the world

hung upon the attainment of an agreement in the United Nations for an international Atomic Development authority such as had been suggested in the Acheson-Lilienthal report and in Baruch's proposal to the United Nations Atomic Energy commission.

Scientists were convinced that there were no defenses against the atomic bomb itself, only against possible carriers. In the event of an atomic bomb race, a nation would have to ring its borders with radar stations on the alert 24 hr. a day for an incoming rocket or aeroplane. Anti-aircraft guns would have to be constantly manned and pursuit planes ready to take to the air on a second's warning. But such a defense would have to be 100% effective to serve its purpose. If a city were attacked by 100 rockets carrying atomic bombs and the defenses stopped 99, the 100th would still be sufficient for the total destruction of the city. There would also exist the danger of bombs smuggled in by saboteurs. Scientists believed that in the event of an atomic bomb race it would be necessary to abandon all large cities and spread the population throughout the countryside so that a bomb might destroy a village but not a city. Factories would have to go underground in deep mines or in tunnels under

It was apparent to everyone that the future of navies must be studied in the light of the Bikini tests. Scientists pointed out that it was not enough to consider the problem of one atomic bomb against a fleet but the combination of several, some exploding in the air, some in the water. It seemed obvious that two atomic bombs, one exploding in the air and the other underwater, would completely wreck any attempt at an amphibious landing. One question that arose was whether a fleet would dare enter a harbour or even narrow waters in time of war.

The atomic bomb converted about one-tenth of 1% of the mass of U-235 or plutonium into energy. Scientists foresaw the possibility of the eventual production of far more powerful bombs, perhaps converting 2% or 3% of some process other than fission. Moreover, they visualized the combination of atomic bombs with many other types of offensive weapons, e.g., rockets travelling in the stratosphere with supersonic speeds. They were convinced that the first 24 hr. of World War III would see the complete destruction of the principal cities of the contending nations. They were certain that World War III would be fought with rockets bearing atomic bombs, with radioactive poison gases easily made as by-products in atomic bomb plants and with methods of biological warfare for the wholesale distribution of blights and rusts, capable of destroying crops and disease germs and viruses capable of starting terrible epidemics among farm animals and human beings.

Peacetime Possibilities.—Physicists believed in 1946 that the development of uranium piles for the generation of power was possible in the near future. The simplest method pictured was to use the energy to heat water to steam which would operate turbine-generators for the production of electricity. Such piles would need extremely careful shielding to prevent the escape of neutrons and harmful radiations into the surrounding neighbourhood. At first it was estimated that such plants could only compete with coal *at \$15 a ton, but it was later agreed that they might even operate at costs below the cost of coal.

Many physicists believed that such power plants might be made small enough to be installed in ocean liners but they did not see how they could be made small enough for use in automobiles or aeroplanes.

· Physicists did not regard uranium fission as the final

chapter in the story of atomic energy. On the contrary, it was only the first. It was entirely within the range of possibility that methods of releasing atomic energy other than fission to convert larger percentages of the mass involved into energy might be discovered.

The knowledge of atomic energy at the close of 1946 could be compared with the knowledge of electricity in the time of Benjamin Franklin. Franklin proved that the destructive lightning bolt was electricity, but man at that time had at his disposal only the feeble static electric machine. There seemed no reason to suppose that the conquest and utilization of atomic energy would not duplicate the history of electricity. It was possible, therefore, that in time atomic energy would cause as great changes in the life of the world as did the introduction of steam and the Industrial Revolution. (See also Chemistry; International Law; Metallurgy; Physics; Standards, National Bureau of; Uranium.)

Attlee, Clement Richard

), British statesman, was born Jan. Attlee (1883– 3, 1883, in London of a middle-class family. He was educated at Haileybury college, Hertfordshire, and University college, Oxford, was admitted to the bar and practised law at Inner Temple (1905-10). He joined the Labour party in 1907 and became a lecturer at the London School of Economics in 1913. During World War I, Attlee joined the army, serving in the middle east and France and attained the rank of major. After the war, he actively engaged in politics and was elected member of parliament for Limehouse (1922). He held important positions in the first Labour government and was chancellor of the Duchy of Lancaster (1930-31) and postmaster general (1931) in the second Labour government. Elected party leader in 1935, Attlee denounced axis aggressions.

On May 10, 1940, Prime Minister Churchill named Attlee lord privy seal and deputy leader of the house of commons in the wartime coalition cabinet. Attlee also held the posts of deputy prime minister and lord president of the council in the Churchill government. He was a member of the British delegation to the United Nations conference in San Francisco (April-June 1945.)

After the Labour party victory in the general elections, Attlee became prime minister (July 26, 1945) and took Churchill's place at the Big Three conference in Potsdam. In Nov. 1945, Attlee, Pres. Truman and Prime Minister Mackenzie King of Canada met in Washington, where they issued a joint recommendation (Nov. 15) for international control of atomic energy. At the opening of the first U.N. general assembly session in London (Jan. 10, 1946), the British prime minister warned that failure to control atomic energy would result in "immense ruin" and virtual "annihilation" of the "most highly civilized portion of mankind." In 1946, Attlee obliquely opposed Pres. Truman's request that displaced Jewish refugees in Europe be permitted entry into Palestine. In the latter part of that year, Labourite "rebels" in commons denounced British foreign policy as having become "too Americanized." Attlee repudiated these charges and criticized, for the first time, Churchill's Fulton (Mo.) speech, declaring that if it was intended to establish an exclusive U.S.-British alliance, "then we do not agree with it."

Attu

See World War II.

Auchinleck, Sir Claude John Eyre

Sir Claude Auchinleck (1884-), British army officer, was born in England, the son of Col. John Claude Auchinleck, He served in India in 1902, and was stationed in Egypt and Mesopotamia during World War I. In 1933 and 1935, he fought with British forces quelling native uprisings on India's northwest frontier. Made commander of the Allied forces in northern Norway in the spring of 1940, Auchinleck took Narvik but had to evacuate the city when the Allies failed to make additional landings in the south. After the collapse of France in the summer of 1940, Auchinleck was appointed general officer commanding the English southern command; he organized England's first defenses against the threatened German invasion. In Dec. 1940, he returned to India as commander in chief, and in July of the next year was made commander in chief of British middle east armies, succeeding Marshal Wavell. Auchinleck's armies in Libya launched an offensive Nov. 18, 1941 and advanced far into Libya but were driven out in June 1942. On June 18, 1943, he was again made commander in chief in India and directed the strategy of Allied forces which repelled the Japanese attempt to invade India from Burmese bases in March 1944. He was promoted to the rank of a field marshal on May 31, 1946, and later was made a member of the executive council that was to serve as India's "caretaker government."

Auckland

The largest city of New Zealand and a thriving seaport, Auckland is situated on the east coast of North Island, capital of the province of its name. Pop. (1945) 300,067. As New Zealand's naval base and one of the cities around which both dominion and large numbers of U.S. soldiers and sailors were quartered or hospitalized during World-War II, Auckland for six years of the decade 1937-46 was strongly affected by war conditions. Those conditions slowed down or stopped all development works except those of a military character, but they also caused acceleration of population growth. The 1945 census figure of 300,067 people (one-sixth of the dominion's total) in the Auckland metropolitan area, compared with 212,159 in 1936. Hence housing needs presented the major immediate postwar problem; expenditure of £100,000 by the city council on temporary and transit accommodation provided but slight amelioration. A peculiarly difficult part of the problem was created by the increase of the Maori population to an estimated 8,000. There was no lack of developmental plans, but there was the familiar shortage of materials and skilled workers to carry them out. The largest work actually begun was the construction of a new waterworks dam at an estimated cost of £275,000, but high priority had been given to a new highway to Whenuapai aerodrome, the terminal of overseas and some internal air traffic. The general problem of transharbour transport with particular reference to the long-mooted harbour bridge was investigated by a royal commission. Additions to the city's facilities before the war included a municipal transport terminal for all buses running to the

suburbs, an Olympic-type swimming pool, the Chamberlain park municipal golf course, a waterfront road to the eastern suburbs and a flying boat base. A park on a headland overlooking the harbour was made in memory of M. J. Savage, the first Labour prime minister, and new botanical gardens were established. A free library system was introduced in Feb. 1946. The city's hospital accommodation was substantially increased by buildings constructed for military purposes. The population of Auckland city (as distinct from the metropolitan area) in 1946 exceeded 212,000 as compared with 102,295 in 1936, with a rateable valuation (annual rental system) of £3,493,000 for 1946–47. Austin, Warren Robinson

Austin (1877—), U.S. statesman, was born Nov. 12, 1877 in Highgate, Vt. A graduate of the University of Vermont (1899) where he received his Ph.B. degree, he was admitted to the bar in 1902. He was chairman of the Republican State convention, 1908. Elected to the U.S. senate, Mar. 31, 1931, to fill out an unexpired term, he was re-elected Nov. 6, 1934 and Nov. 5, 1940.

His background in foreign affairs was broad and varied. He was the legal representative in China for U.S. interests engaged in building railroads there in 1917, studied conditions in Palestine under the British mandate in 1936 and made a study of the Puerto Rican legal system in 1937.

Austin campaigned against the League of Nations in the period after World War I, although he consistently supported U.S. participation in the World Court of International Justice. During his tenure as member of the senate foreign relations and military affairs committees, he changed his views on U.S. participation in a world peace organization in the 1930s and endorsed, in the main, the administration's foreign policy. He also took a leading role in the fight to amend the Lend-Lease act and was co-author of the first Selective Service act enacted in 1940. On June 5, 1946, President Truman named Austin U.S. representative on the United Nations Security council, and on July 18 he was named head of the U.S. delegation to the U.N. General assembly. The following month he resigned from the senate to devote all his energies to his new tasks.

Australia, Commonwealth of

A self-governing member of the British Commonwealth of Nations, Australia was formed by the federation of the six colonies (later states) of New South Wales, Victoria, Queensland, South Australia, Western Australia and the island state of Tasmania, and comprises also the Northern Territory and the Australian Capital Territory. Language, English; religion, Christian (census 1933: Anglicans, 2,565,118; Roman Catholics, 1,161,455; Presbyterians, 713,229; Methodists, 684,022; other Christians, 603,914; nil or not stated, 860,602). Australia lies in the southern hemisphere between longitudes 113° 9' E. and 153° 39' E. and latitudes 10° 41' S. and 43° 39' S. Total area: 2,974,581 sq.mi., nearly 40% lying within the tropics. Chief towns (pop. est.): Canberra, A.C.T. (capital) (12,200), Sydney (1,398,000); Melbourne (1,170,000); Brisbane (370,500); Adelaide (362,500); Perth (263,000); Hobart (70,800). Pop. (census 1933) 6,629,839; (est. June 30, 1946) 7,446,300.

There were, in addition, about 47,000 full-blood aboriginals (1944). About 98% of the population was of British stock

Prime ministers during the decade 1937–46: Joseph Aloysius Lyons (Jan. 6, 1932–April 7, 1939); Sir Earle Christmas Grafton Page (April 7, 1939–April 26, 1939); Robert Gordon Menzies (April 26, 1939–Aug. 29, 1941); Arthur William Fadden (Aug. 29, 1941–Oct. 7, 1941); John Curtin (Oct. 7, 1941–July 5, 1945); Joseph Benedict Chifley (after July 13, 1945).

Small State, Large Role.—The history of Australia in the decade 1937–46 was largely the record of a swift revolution in military and industrial development, and no less of a rapidly growing awareness of the large part which circumstances were constraining a small people to play in world affairs. Vast distances and geographical isolation became almost overnight a menace rather than a protection; and with the loss of natural security from foreign attack there vanished also the last traces of a mentality which had regarded local defense measures as an expensive insurance against contingencies remote to the point of impossibility.

In 1937 defense had to compete with the quest for material prosperity. The world depression of the early '30s had struck the vulnerable Australian economy with great severity, and it was not until 1937 that its effects had been finally left behind. In the middle of that year export prices, an infallible index to Australian prosperity, reached a high peak; unemployment fell to a tolerable level; real wage rates were increased; and the balance of trade became exceptionally favourable. Taxes were substantially reduced, and the last of the depression "cuts" in civil and war pensions and government salaries were restored. The dispute with Japan over the ill-starred "trade diversion policy" of 1936 had been settled, and Japan had resumed the purchase of Australian wool.

In the years before the outbreak of World War II only 1½% of the national income was provided for defense, and plans were made for a resumption of migration. A national insurance act in Jan. 1938 provided for general sickness and disablement benefits and a gradual transition to contributory old-age pensions, with unemployment insurance to follow. But the early promise was not fulfilled. A serious drought was experienced at the beginning of 1938, and export prices fell heavily. They remained unsatisfactory for the next two years, and the internal economy continued to give grounds for anxiety until the outbreak of war.

The Lyons coalition government (United Australia and Country parties) was returned to power in Oct. 1937, pledged to its national insurance proposals and a stronger defense policy which the Labour party had attacked as evidence of a suspected trend towards "foreign entanglements." In March 1939 R. G. Menzies resigned in protest against a decision to postpone the national insurance scheme, which was thought in some quarters to be incompatible with the pressing needs of defense. In the following month J. A. Lyons died, and the coalition collapsed with hard words after the election of Menzies as leader of the United Australia party. The new Menzies government met parliament only briefly before the outbreak of war put an end for the time being to the dissensions which had threatened its existence.

Preparation for war, though meagre in those three years, had not been entirely neglected. Lyons' proposals in May 1937 for a Pacific pact of nonaggression were followed within a few months by Japan's attack on China. Popular revulsion was immediate and widespread, but official policy, tied to that of Britain, stopped short at participation

in the mild protests of the League of Nations. A trade arrangement was negotiated in July 1938, but popular feeling was again revealed in Jan. 1939 when wharf labourers refused to load pig iron for Japan. News from the other side of the world was no better. In Sept. 1938 Lyons had declared that Australia stood with Britain on the Czechoslovak issue, but official leanings towards conciliation and caution were accompanied by a growing feeling that war could not be staved off much longer.

Defense preparations quickened appreciably during 1938. A three-year program for the expenditure of \$171,-000,000 was announced in March and in December was raised to \$234,000,000, largely in response to popular reaction to Munich. There was also considerable public support for the reintroduction of compulsory military training, suspended in 1929 by the Labour government of that day; but this was not done until after the outbreak of war, and then with a pledge that there would be no conscription for overseas service. Preparations on the industrial side were pushed ahead. The foundations of an aircraft industry were laid, and scientific and economic investigations into the availability of strategic materials set under way. In March 1939 it was decided to compile a national register of manpower, and the registration of wealth was added later in an endeavour to placate Labour hostility to anything savouring of industrial conscription. An industrial advisory panel was appointed, a register of productive capacity of defense significance compiled, and in June a new department was created to concentrate on problems of military supply and industrial development.

With events marching to their climax, Menzies in Aug. 1939 announced Australia's firm resolve to stand with Britain, whatever the consequences. On the evening of the day on which Great Britain declared war (Sept. 3), Australia was also at war with Germany. Within a few days a national security act gave the government almost unfettered power to make regulations in respect to matters affecting the prosecution of the war, but specifically excluded the power to impose military conscription for serv-

Within rifle shot of the fighting front Australian troops in New Guinea cast their votes in the federal elections of 1943

ice overseas or industrial conscription in any form.

First Two Years of War.—For two years Australia's territory remained uneasily free from foreign attack. But its resources were organized to build up its own defenses; to provide, equip and feed expeditionary forces and to assist in supplying the sinews of resistance to Britain and its dwindling band of allies. Immediately upon the declaration of war, action was taken to place the economy on a war footing. Overseas exchange transactions and coastal shipping were brought under control, price control was initiated and arrangements were made for the purchase by Britain of the wool clip and surplus food products. All exports were brought under licence, and overseas credit resources were mobilized for national use.

During the next two years these measures were refined and extended, and new controls were introduced. In order to conserve dollars for urgent war purchases, civil imports from "non-sterling" countries were progressively limited to the barest essentials. During 1940 restrictions were placed on the raising of new capital and the construction of buildings, and on the right of skilled metal tradesworkers to leave their jobs. In December a new department was established to organize and mobilize all labour and manpower resources. In early 1941 shipping and coal were brought under closer control, and a limited measure of rent control was introduced in March. With oversea shipping dwindling, the primary industries were reorganized, land sales were controlled, a merchant shipbuilding program was initiated and imports were further restricted.

At the outbreak of war the Australian army comprised a partly-trained militia force of 80,000 men. It was immediately decided to raise a special volunteer force of 20,000 men for service at home or abroad, and at the end of October to reintroduce compulsory military training for home defense as of Jan. 1940. The volunteer force (the second Australian imperial force) was progressively built up during 1940 to four divisions with corps troops. The training and equipment of the augmented militia forces was also vigorously pushed forward, under a plan intended to provide a home defense force of 250,000 men. During 1941 the strengthening of the second A.I.F. continued, and a division was sent to reinforce the Malayan defenses. As the Japanese threat became more menacing, the expansion and training of the home defense force was accelerated. By the end of 1941 the A.I.F. at home and abroad had a total strength of 200,000 and the total armed forces then in the commonwealth numbered more than 250,000.

Early decisions to send a small air expeditionary force to Britain were modified at the end of Oct. 1939 in favour of heavy participation in the new empire air training scheme. Australia's initial objective under this scheme was the training of 26,000 aircrew members by March 1943 and 10,000 aircrew members a year thereafter. Concurrently, Australia's own air force had to be built up. The immediate response was overwhelming, and the training scheme was constantly ahead of schedule. By the end of 1941 many more than 200,000 had volunteered for enlistment in the Royal Australian air force and more than 50,000 men had been selected for training under the empire scheme. When it ended in March 1945, Australia had supplied 37,057 aircrew members, three-quarters of whom had been fully trained in Australia, and large numbers of ground staff.

The exploits of the second A.I.F. and Australian naval and air forces in the middle east and north Africa were written into world history. They were in the forefront of

the Libyan campaign which carried Sir Archibald Wavell's army to Bengasi in Feb. 1941 but left one Australian division and a British armoured brigade in April to hold out for many long months in the historic siege of Tobruk. In the meantime, Australian forces played an important part in the campaigns in Greece, Crete and Syria between April and July 1941. The withdrawal to Australia of a large part of the seasoned veterans of the A.I.F., in the face of peril to the homeland, came towards the end of the drive which carried the British beyond Bengasi by the middle of Jan. 1942. Thirty thousand Australians, however, formed the spearhead of Gen. Bernard L. Montgomery's great offensive from El Alamein on Oct. 23, 1942, which marked the beginning of the end of German power in North Africa.

The activities of the fighting forces during the first two years of war were backed up by a growing industrial effort at home. Until the fall of France there was some failure by the people to appreciate the full scale of impending dangers, and the war effort was somewhat hampered by early administrative weaknesses and political differences. The difficulties were aggravated by a serious coal strike from March 11 to May 20, 1940. Thereafter war industry began to stride forward. A ministry of munitions was set up in May, and a vast production program was initiated which eventually turned Australia into the greatest Allied arsenal in the far east. During 1941 it was producing, in addition to many of its own machine tools and most of its heavy equipment, ammunition, small arms, grenades, bombs, mines, gun forgings, automatic weapons, anti-aircraft, naval and antitank guns, 25-lb. howitzers, and small naval craft. By the end of the year, more than 1,000 Australian-made aircraft were in service, and good progress had been made toward the manufacture of aircraft engines and heavy bombers and fighters.

It was remarkable that so much was achieved in the first two years of war with the political balance so precariously poised. In March 1940 the Country party rejoined the government, but repeated efforts to form a fully national government met with no success. In September the government's majority was reduced to one in the lower house and two in the senate, but further negotiations for a national government resulted only in the formation of an advisory war council without executive powers. Later rebuffs were accompanied by marked signs of discontent within the government's own ranks, which was diverted but not entirely allayed by the reorganization of the ministry accompanying the prime minister's "prospectus of an unlimited war effort" at the end of June 1941. A final offer by Menzies to give Labour half the representation in a national government and even to serve under John Curtin was rejected, and Menzies' resignation was announced on Aug. 28. The government formed by A. W. Fadden, leader of the Country party, was defeated on Oct. 3 on its budget proposals by the votes of two non-Labour independents. Curtin then set about forming the Labour cabinet which survived almost unchanged until his death on July 5, 1945.

One of the first acts of the new government was to bring the policy of the private banks effectively under the control of the Commonwealth bank and to limit their ability to make inflationary loans and excessive profits. A month later, rent control was widely extended, and rentals were pegged at approximately prewar levels. The new government achieved a place in history founded largely on the vigour and courage with which it carried out war policies which, for the most part, were basically repugnant to prewar Labour ideals.

War in the Pacific.—For Australia, the attack on Pearl Harbor and the fall of Singapore ushered in a new phase of the war, with invasion an imminent possibility and most of the trained fighting men, naval forces and operational air squadrons heavily committed thousands of miles from its own shores.

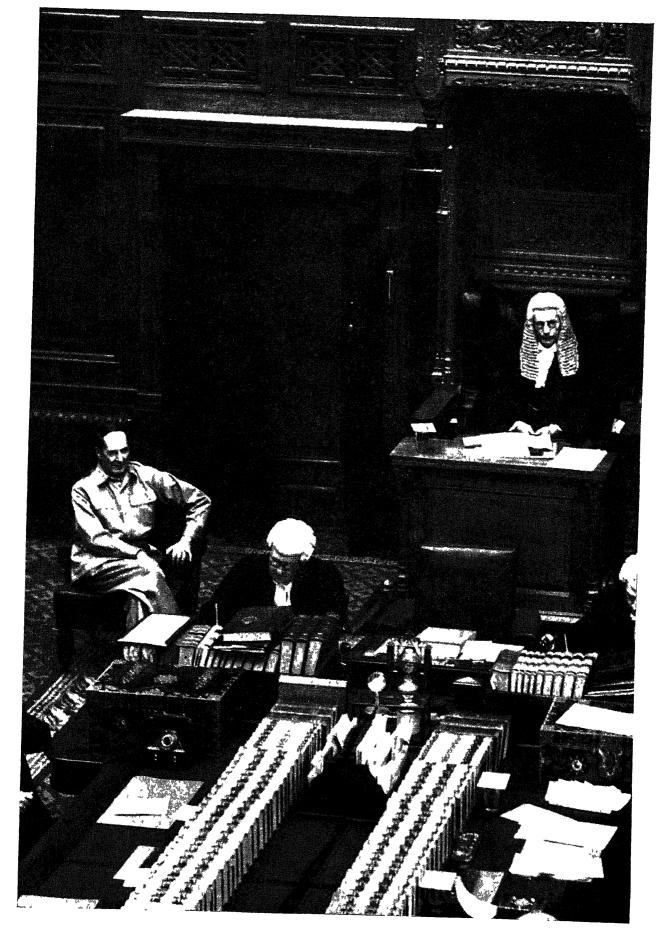

The home defense forces and those members of the A.I.F. still in Australia were immediately swung into defensive disposition, and naval and air forces were alerted for possible enemy raids. Transport services were placed under emergency control. Darwin's defenses were strengthened, blackouts were imposed in coastal areas and civilian defense arrangements were hurriedly completed. Holidays and leave for industrial and commercial workers were summarily suspended, and extensive overtime was ordered in war establishments.

Disaster came early. Within a few weeks Malaya had fallen, and most of an Australian division was in Japanese hands. Burma and the Netherlands Indies followed within a few months. In the meantime, the Japanese occupation of Rabaul and Kavieng at the end of Jan. 1942 threatened allied supply routes to Java and Australia. Port Moresby was bombed on Feb. 3 and regular air raids on Darwin began on Feb. 19.

It was in these circumstances that Australia turned to her friends for assistance. Under great difficulty, Britain agreed to find shipping to return a substantial proportion of Australian forces from the middle east, and expedited the supply of war equipment which was sorely lacking. Curtin had already made it clear, in a New Year message which aroused some passing controversy, that Australia "looks to America free of any pangs as to our traditional links of kinship with the United Kingdom." Australia did not look in vain, for it was chosen as the main base in the Southwest Pacific. Within a few months U.S. forces and equipment were arriving in ever-growing volume. And from the Philippines came Gen. Douglas MacArthur, under whose operational control Australia placed the army, units of the navy and 49 air force squadrons.

Meanwhile, Australia looked also to itself. Volunteers poured into the A.I.F., and large numbers of men were called into the militia. But the great need was for war material, and the government and the people set out to produce it at any cost. The cost included a complete revolution in the industrial economy, and the imposition of economic and social controls so fundamentally opposed to traditional Labour policy that possibly only a Labour government could have enforced them. Civilian industry was rapidly curtailed to free labour for national service. In Feb. 1942 severe restraints were placed on the freedom of workers to leave their jobs and of employers to hire and fire, and the allocation of manpower to industries and the services was brought under central direction on the principle of "work or fight."

At the same time, an executive body with full powers of conscription—the Allied Works council—was established to carry out the huge program of construction required for home defense and the offensive needs of the rapidly-growing Allied forces. To prevent the new pressures from leading to financial disorganization, sweeping measures were introduced to freeze wages, profits, land values and share prices at their then current values. In the following

years these measures were extended, adapted and supplemented as the industrial economy reacted to the successive pressures to which it was subjected. Rationing of consumer goods was introduced during 1942 and was reinforced by an "austerity campaign." Uniform income taxation by the commonwealth was forced on the states in the middle of that year, and upheld by the high court as a valid exercise of powers available even in time of peace. In April 1943 a rigid price ceiling was imposed, supported by subsidies. In the same year income-tax rates were raised to unprecedented levels, and in the last year of the war more than 40% of war expenditure was being met from current revenue.

Regimentation and austerity were accepted as the price of immediate salvation and ultimate victory. After the fall of Java further Japanese landings were made on the northeast coast of New Guinea, and the elimination of Port Moresby, the key to the defense of the Australian mainland, became the first Japanese objective. A largescale attempt by sea in the first week of May 1942 was smashed by Allied sea and air forces in the battle of the Coral sea. It was followed by a frontal assault across the towering Owen Stanleys, combined with a sea-borne attack on Milne bay to provide a base for air support from the eastern flank. The Japanese force which landed at Milne bay on Aug. 26 was flung back into the sea by Sept. 5. The attack from Buna met with more initial success, and the Japanese were within 35 air miles of Port Moresby by the end of September. Then began the long fight back over the historic Kokoda trail, to end, after desperate fighting, with the Australian capture of Gona on Dec. 9 and the capture of Buna and Sanananda by Australian and U.S. forces in Jan. 1943.

The Papuan campaign was followed immediately by the repulse of a Japanese attack on Wau, and a months'long pursuit of the Japanese forces. But Japanese strength was still being built up steadily throughout the northern islands, with nearly 250,000 troops disposed in an arc reaching from Bougainville to Timor. Fears of an attack on the mainland from the northwest were reduced by the great battle of the Bismarck sea in the first four days of March, when a large and heavily-protected Japanese convoy was completely wiped out. By June the Allied forces were on the offensive. While U.S. troops were driving through the central Solomons the Australians, with U.S. support were clearing the Japanese from the Huon peninsula. This campaign, which ended with the link-up of the Australian and U.S. forces near Saidor in Feb. 1944, opened the way for MacArthur's leap-frog advances along the northern New Guinea coast and into the neighbouring islands.

As MacArthur went west and north through Morotai to the Philippines with United States forces and some Australian naval and air support, it became the Australian task to attack and to contain nearly 150,000 Japanese bypassed in his spectacular moves. The Wewak-Aitape area was taken over in November, and more than 90,000 Japanese were gradually pushed back in the Gazelle peninsula after landings in New Britain in the same month. In Dec. 1944 two Australian divisions took over from U.S. troops at Torokina. In an 11-weeks' campaign beginning in May 1945, two veteran Australian divisions substantially completed the reconquest of Borneo. The success of the Australian operations was facilitated by the superiority achieved and maintained by the U.S. air forces.

It was only the unparalleled success of the initial opera-

tions which prevented Australian divisions from fighting with U.S. in the Philippines. Six divisions were in action when the war ended, and the equivalent of ten had been committed during the long campaign in New Guinea. At their maximum war strengths the Australian navy was 8 times, and the air force 60 times, their respective prewar strengths. Danger of embarrassment from the limitation on the use of the militia to Australia and its territories was reduced at the close of 1942 by Curtin's largely personal success in inducing his party to approve its use south of the equator in the Southwest Pacific area, and ended by the great increase in the strength of the volunteer A.I.F. by new recruitment and transfers from the militia. While there was some criticism of Labour policy in early 1943, the bitter conscription controversies of World War I were largely avoided. By the end of 1944, about 95% of the army combat forces, as well as the whole of the naval and air forces, had volunteered for service in any theatre of war. After 1943, embarrassment of the war effort seemed more likely to arise from industrial manpower shortages than from any lack of front-line fighters. These became acute as growing U.S. forces in the Pacific looked to Australia for much of their food, clothing and other war supplies; and when the pressure from that quarter relaxed its place was taken by new demands arising from the basing of the British Pacific fleet on Australia from the end of 1944. (See also World War II.)

Reconstruction.-When hostilities ceased, the Australian economy was extended almost to breaking point. Inflation had been kept at bay by a strong financial policy and rigorous economic controls. But total war left in its train acute shortages of civilian goods, a desperate housing situation and a labour force that was clearly showing the strain of six years of war. The new needs of demobilization and reconstruction offered little immediate relief. Early thought had been given to the problems that would follow the postwar contraction of the commonwealth's wartime powers, and in Sept. 1942 constitutional amendments were proposed to give the commonwealth sweeping economic and social powers. Intense hostility to the commonwealth's proposals was manifested in November at an all-party convention of commonwealth and state representatives, but a unanimous compromise eventually emerged from the welter of conflicting social philosophies, party loyalties and local prides. The state premiers and opposition leaders agreed that the state parliaments should be asked to "refer" to the commonwealth until five years after the cessation of hostilities a fairly wide but specific list of powers. Notwithstanding their unanimity, the agreed bill came in for so much opposition in the states that it was passed in a workable form only in New South Wales and Queensland. The commonwealth therefore decided in March 1944 to submit to the people proposals to amend the constitution to much the same effect. At the referendum in August of the same year they were rejected by a substantial majority. Thereafter there was little prospect of the full powers being "referred" by all the state parliaments, though their governments were willing in 1946 to delegate to the commonwealth temporary control over prices, rents, capital issues and land values. In the meantime, following doubts cast by a high court decision on the legality even of existing social services, it was decided to seek power to make laws in relation to marketing, social services and employment at a referendum held concurrently with the 1946 elections. The social services power was granted, but the marketing and employment proposals were narrowly rejected.

Curtin had given a pledge of "no socialization during

the war" in his overwhelmingly successful 1943 election campaign, but his government did not entirely lose sight of its own social policies even during the darkest days of the war. Pensions were granted to widows in June 1942. In March 1943 a substantial national welfare fund was created to finance proposed new social services, and in April war pensions, repatriation benefits and maternity allowances were increased. In April 1944 a non-contributory sickness and unemployment benefit scheme was approved, but a "free medicine" scheme was later held to be ultra vires. In June 1945 civil pensions, after increases in 1942 and 1944, were raised by 20%; and child endow-

ment, first introduced by the Menzies government in 1941, was increased by 50%. A hospital benefits act came into operation in the first half of 1946, and in August the means test for civil pensions was liberalized. Little other legislation of a distinctively party flavour was attempted during the war. In March 1943 a mortgage department of the Commonwealth bank was approved to make long-term loans to primary producers. During Curtin's temporary absence the government announced in Nov. 1944 a plan to nationalize the interstate airways, but after some delay the high court refused to recognize the monopoly.

In the month in which hostilities ceased, however, ap-

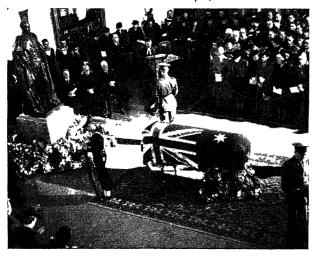

proval was given to comprehensive legislation introduced five months earlier to make permanent the main features of the wartime banking regulations, and to make the management of the Commonwealth bank responsible to the government in matters of broad policy. In Oct. 1945 parliament ratified agreements with the state governments providing for rental rebates to low-income tenants under government housing schemes, and in Aug. 1946 an act was passed to authorize a far-reaching scheme of reorganization of the coal industry.

Planning for reconstruction had begun in 1941 but was interrupted by Japan's entry into the war. A separate ministry for reconstruction planning was established at the end of 1942. In the following year, commissions were appointed to report on housing, rural reconstruction and the development of secondary industries, and the states were brought into a national works council to plan postwar public works. In May 1945 the government announced as the guiding principle of its postwar economic policy the pursuit of "full employment." About the same time a comprehensive act was passed governing the rights of ex-servicemen to rehabilitation benefits and reinstatement in old or preference in new employment. Its most controversial feature was the limitation of preference to a period of seven years, which represented a compromise between the wider demands of ex-servicemen and the reluctance of the labour movement. Demobilization was accomplished quickly, notwithstanding the need to disarm and guard large Japanese forces in the islands and to provide troops for the occupation of Japan. Re-employment presented fewer difficulties than might have been expected from Japan's unexpectedly sudden collapse.

The achievements of the Curtin governments during the war and of the Chifley government after Curtin's death formed the main theme of Labour campaigning in the elections of Sept. 1946. The Liberal (formerly United Australia) and Country parties stressed the need to look to the future. In the result, the Labour party was returned to power, though with some reduction in the large majority it had enjoyed from 1943. (See also New Guinea.)

Australian Literature

In the Australian novel and the short story, a greater variety of theme was employed during the decade 1937-46; writers showed a more complete assimilation of native environment. Xavier Herbert's Capricornia (1938) took a sociological attitude to the aborigines of the northeast, treating them as human beings caught in the struggle for adjustment with white civilization. Kylie Tennant wrote of working-class surroundings in The Battlers and Foveaux (both 1938); and later published Ride On, Stranger (1943). Leonard Mann in The Go-getter (1942) also wrote a grim economic depression tale and in Mountain Flat (1939) had dealt with the passions and greed for the land of settlers in a Victorian country district. A writer whose reputation was established during the period was Eleanor Dark, with Sun Across the Sky (1937) and Waterway (1938), both analytical novels; in The Timeless Land (1941) she presented a brilliant historical novel of the period of the first settlement of the continent. Miss M. Barnard and Flora Eldershaw continued their collaboration under the pseudonym of M. Barnard Eldershaw, with Plaque with Laurel (1937) about Australian literary people. A further novel by Henry Handel Richardson (Mrs. J. G. Robertson) was The Young Cosima (1938), a study of the Wagnerian circle. Katherine Susannah Prichard continued her realistic novels of western Australian country life with Intimate Strangers (1937); her Moon of Desire was more romantic. William Hay, in the Mystery of Alfred Dowbt (1937), returned as an important contributor to the Australian novel. In 1939, Miles Franklin collaborated with Dymphna Cusack in a satire Pioneers on Parade and in 1946 published My Career Goes Bung. In Legend for Sanderstead, Vance Palmer faithfully portrayed a north Queensland setting. Pastoral Symphony (1939) by J. J. Hardie, and The Pea Pickers (1940) by Eve Langley, were also

The short story had many able exponents, among them Myra Morris, James Hackston, Henrietta Drake-Brockman, Don Edwards, George Farwell and d'Arcy Niland, whose work appeared in various journals. F. Dalby Davison published The Woman at the Mill in 1940. Gavin Casey, a writer of quality whose dramatic stories had humour and optimism, published first It's Harder for Girls (1942) and later Birds of a Feather (1945). In The Persimmon Tree (1944) Marjorie Barnard drew women characters with psychological insight, and Margaret Trist dealt with homely situations and family relationships in The Sun (1943). James Brian showed quiet humour in First Furrow (1944) and Alan Marshall's These Are My People (1945) was rich in atmosphere and characterization. Katherine Susannah Prichard published Potch and Colour in 1945, and in the same year appeared A Girl with Red Hair by Douglas Stewart, a New Zealander, resident for some years in Australia, whose stories were

remarkable for polished diction, imagery and intensity.

The period was rich in poetry. Two schools were represented by *The Jindyworobak Anthology* and *Meanjin Papers*. The Jindyworobaks drew their inspiration from the Australian environment and rejected verbiage suggestive of European surroundings. The Meanjin school was more universal in approach and outlook. The schools were not exclusive and stimulated contemporary verse. Rex Ingamells, editor of *The Jindyworobak Anthology*, published several volumes, including *Content Are the Quiet Ranges* (1943).

Gina Ballantyne published delicate verse in *Phantom* (1942) and *Vagrant* (1943). William Hart-Smith, in *Columbus Goes West*, used economy of words and showed breadth of sympathy. Flexmore Hudson published *In the Wind's Teeth* (1940), *Indelible Voices* (1942) and *With the First Soft Rain*. Brian Vrepont used experimental forms in *Beyond the Claw* (1943). In 1940, Paul Grano published some outstanding lyrics. Perhaps the most intellectual poet in Australia, R. D. Fitzgerald published *Moonlight Acre* in 1938. In 1944, Kenneth Slessor published *roo Poems*. In *Adagio in Blue* (1938), T. Inglis Moore wrote in lyrical mood; but in *Emu Parade* (1941) was disillusioned. *Poets at War* (1944), compiled by Ian Mudie, contained the work of nearly 80 servicemen.

Australian drama showed development and the work of Dymphna Cusack in *Red Sky at Morning* (1942), Douglas Stewart's *Ned Kelly* (1943) and Helen Drake-Brockman's *Men without Wives* was notable.

Austria

Austria is a nation in central Europe; area 32,360 sq.mi.; pop. (est. 1939) 6,694,782, more than 90% Roman Catholics. Almost the whole population is German-speaking. Capital: Vienna, with a pop. (1939) of 1,918,462; other leading cities are: (1939) Graz (210,175); Linz (131,423); Innsbruck (80,084); and Salzburg (79,264). Austria is a federal state consisting of eight provinces (Lower Austria, Upper Austria, Salzburg, Styria, Carinthia, Tirol, Vorarlberg, Burgenland), and a mediatized city, Vienna. Austria was an independent republic from 1918 until March 13, 1938. Its last president prior to World War II was Wilhelm Miklas (re-elected Oct. 9, 1931), its last federal chancellor Dr. Kurt von Schuschnigg. After the restoration of Austria in 1945, Dr. Karl Renner became chancellor. At the end of Dec. 1945 he was elected president, and Leopold Figl became chancellor.

Losing Struggle.—Around the middle of 1937, the fate of Europe for the succeeding ten years had been decided. The united front of the big European powers for the maintenance of the status quo, and for the frustration of Hitler's aggressive tendencies, had finally collapsed.

Around the Spanish Civil War, two groups of countries had crystallized, opposed to each other for political, economic and ideological reasons. On the one side were the western democracies and the soviet union; on the other Germany and Italy with their growing sphere of European influence, to which Poland and Yugoslavia belonged at that time no less than Hungary.

At the focal point—the middle Danube—the independent and free state of Austria was situated. After Jan. 1933, this country had fought a desperate battle for existence with Hitler. The annexation of Austria had been Hitler's first acknowledged aim. National socialist Ger-

many at first tried to achieve this objective through economic strangulation by means of an all-embracing boycott, which was to prevent all commercial and tourist traffic. When this did not have the desired results, Hitler began to expend large sums of money to corrupt the inner administration of Austria and to create a revolution in the country. A bloody civil war in July 1934 resulted, in which the Austrian chancellor, Dr. Engelbert Dollfuss, was murdered. A deputy of the German reichstag, Theo Habicht, had until that time been in charge of the conquest of Austria from within; he was recalled when Dollfuss was murdered, but the revolution had failed through the resistance of the Austrian people. Significantly, however, Habicht was at once made mayor of a large city in the Rhineland and later undersecretary of state in the German foreign office.

The Austro-German frontier was the country's longest, stretching for hundreds of miles; in the east Austria bordered on Hungary, a friendly country, but with very close economic ties to Germany, in the southeast on the outspokenly hostile and Germanophile Yugoslavia of Premier Stoyadinovich, in the north on Czechoslovakia, a good neighbour who, however, was threatened by Germany just as much, and in the south on Italy.

To meet the German threat—for there was no other threat to the independence of the Austrian state—Austrian policy tried to use various means.

In foreign policy, the government tried to obtain an international guarantee for Austria; the idea of such a guarantee was an obvious one, as Austria had been ordered by the Covenant of the League of Nations and by subsequent treaties to maintain its independence under all circumstances. This duty had remained in force, and the large powers had confirmed repeatedly that they wished to see the national independence of Austria maintained, but beyond that no formal guarantee had been given.

In economic policy, Austria had made far-reaching agreements with its neighbours Italy and Hungary (Roman Protocols, 1934), including a political alliance to maintain the independence of Austria.

In interior policy, there was a strong concentration of the whole political leadership in the hands of a government nominated by the elected head of the state. Parliament was dissolved in 1934 after it had agreed on a new constitution, which replaced political parties by a system of corporations. The political parties were dissolved and their further existence forbidden, as this was the only way in the view of the government to prevent Austria from being overrun by a nazi party led and financed by the German reich.

The farther Italy moved away from the policy of the great powers and thereby associated itself with Germany, the more doubtful became its support for Austria. Because of the general state of tension in Europe, caused at first by the Ethiopian conquest and later by the Spanish Civil War, Hitler was increasingly successful in obtaining a free hand. The position of the unprotected Austrian state was therefore becoming increasingly precarious. For that reason Austria began to negotiate directly with Berlin, trying to persuade Hitler to give formal and legal recognition to the national independence of Austria, to put an end to the economic war, and to undertake not to interfere in the internal affairs of the country.

A treaty along these lines was actually obtained. In the agreement of July 11, 1936, Hitler for the first time recognized the independence of Austria.

It was obvious from the first that Hitler did not mean to keep this agreement; he left no doubt as to that in private conversations which were reported from time to time. But it was just as obvious that Hitler, for reasons of foreign policy, had decided to create the impression for the time being that he had given up his aggressive designs in central Europe. He expected that such an action would help to ease the alarm which the remilitarization of the Rhineland (1936) and the increasing re-armament (1935–37) had provoked in Great Britain and France. Hitler's desire for a temporary state of tranquillity in Europe gave rise to justified Austrian hopes for gaining time. But in 1937 it became increasingly obvious that Hitler wanted to regain a free hand. The old policy of political provocations was started again.

The friendship between Berlin and Rome was getting closer in all respects. Italy informed the Vienna foreign office after Mussolini's famous visit to Berlin in Sept. 1937, that the Italian position with respect to Austria had not changed, and that the Austrian question had not been discussed in Berlin and Rome, but there were many signs which disproved this diplomatic talk.

In the fall of 1937, the Vienna police finally discovered a secret plan for a National Socialist revolution in Austria which was to be supported by an invasion by the German army. Incidents were to be provoked artificially to cause the uprising and to present Germany with a formal reason to intervene, The material found showed clearly that the plan had been made in agreement with nazi party offices as well as with official German support.

Austria answered with a diplomatic protest and attempted to obtain from Hitler a confirmation of the treaty of July 11, 1936.

Austria considered it important to gain still more time, as reliable information indicated the possibility of a rapprochement between London and Rome. Austria felt sure that Hitler would not attack as long as he was not certain of close ties with Italy to guard his southern frontier. On the other hand, Austria had to consider that the German general staff would want to occupy the Inn valley (north Tirol), because it considered an effective defense of southern Germany impossible without it.

In Jan. 1938, Hitler, through Franz von Papen, the German ambassador to Austria, invited the Austrian chancellor Kurt von Schuschnigg, to visit him in Berchtesgaden. To obtain an acceptance of this invitation Hitler expressly agreed that he was prepared to reaffirm the independence of Austria, and to forego all interference in its internal affairs. There were not to be any new demands. The visit came about on Feb. 12, 1938.

Hitler-Schuschnigg Meeting.—Many descriptions of the meeting at Berchtesgaden, published subsequently by presumably informed sources, were pure invention. Some were disseminated by the nazis themselves for propagandistic purposes. In reality, only a bare minimum of etiquette customary to international relations was observed at the meeting. Even Hitler's personal behaviour was not surprising, despite the fact that the meeting was unique and without precedent. The Austrian negotiator was prepared for anything, even for one of the motorcar accidents which had marked diplomacy in the third reich. He placed no great faith in Hitler's advance assurances of Germany's will for Austrian independence.

The visit at the Berghof lasted for almost 12 hours without interruption. It was so staged that most of the conversations were face to face—again not in conformity

with the usual international protocol. Hitler's gestures and his voice were quite in keeping with the attitudes made famous through news photographs, motion pictures, the radio and even the pages of *Mein Kampf*. The only difference for Schuschnigg was that he was now face to face with the fuehrer.

The development of Hitler's ideas was absolutely in conformity with mass-meeting standards, essentially thus:

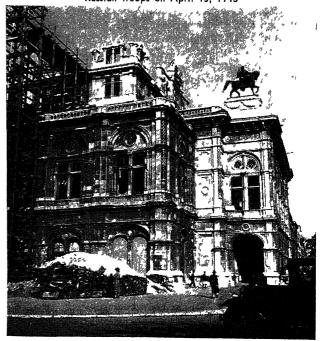

"The rise of an obscure soldier to leadership of the Germans has brought the creation of a class-less, party-less, socially unprejudiced, unified people, not split by denominational conflict. All of Germany's neighbours belong to this nation, insofar as they are German-speaking. I am about to fulfil a historic mission, guided by providence, from which no one will deter me. Thus far I have achieved everything I have set out to do, and so have become the greatest German of history. Austrian history, including that of the Habsburgs and the Catholic church, has been one great series of treason against the people. This nonsense must be put to an end. Therefore, I have decided to solve the Austrian problem once and for all. One week from now, I will step before the German reichstag to report on the course of events. Therefore, I have no time to lose. If we arrive at no conclusions, I will have to make my own decisions tomorrow night."

(The character of these decisions was adequately conveyed by the simultaneous, provocative presence of the staff generals of the Wehrmacht at the Berghof!)

"Austria should by no means believe that I am bluffing, nor should it expect help from any source. I am in agreement with Mussolini. France is in no position, and England is not willing, to help Austria. If you are reasonable, you will be able to enter your name in history alongside those of other great Germans like Goering, etc. If not, everything else will take its course of its own accord."

Thus the state of affairs was clear; Hitler's decision left no room for doubt. The British diplomat with whom Hitler claimed to have discussed the German claim to

Vienna's state opera house, showing the damages resulting from the bombing and fighting prior to the capture of Austria's capital by Russian troops on April 13, 1945

"Austrian liberation" only a short time before in that very same room, had voiced no objections, according to the fuehrer. Assuming the story was true, that diplomat could have been only Lord Halifax or Ambassador Nevile Henderson.

Finally, Hitler presented Schuschnigg with a list of demands which bore the character of ultimatums and specified deadlines. Evidently he had only the vaguest and most superficial conception of the list's contents, and did not permit any discussion thereof. The responsible authors were probably in Austria.

According to these demands, the Austrian government was to appoint a National Socialist (Arthur Seyss-Inquart) as minister of police, decree general amnesty for all nazis and grant full political equality to all National Socialists.

Hitler, however, declared his definitive recognition of Austrian sovereignty and its constitution, as well as his willingness not to interfere in internal Austrian affairs. This "guarantee" was the condition under which Schuschnigg had agreed in the first place to go to Berchtesgaden.

Hitler's "treaty" was signed as the optimum achievable at the moment. Otherwise a march on Austria by German troops that very night would have been the strongest probability. After signing the document, Hitler declared his belief "that there would be peace for five years now"; that he "would like to spare the world another war, but, unfortunately, wasn't being heeded"; and that, after all, he was "about to arm the best Wehrmacht in German history, and it would be foolish not to use such a splendid instrument."

For all intents and purposes the independence of Austria had been lost. Hitler nominated a new gauleiter for Austria as early as Feb. 13, 1938. Hitler thus violated his promise of non-interference in internal Austrian politics the very day after he signed the agreement.

In the succeeding weeks, Germany, in spite of all promises, tried to force Austria to make new concessions to give up its independence, and tried to achieve this aim openly by creating disturbances in the country.

Schuschnigg therefore ordered a universal and free plebiscite to be held, which was to prove that the majority of the Austrian people wished their country to remain free and independent. The proposal to be voted upon merely contained the declaration which Hitler himself had confirmed in writing on Feb. 12, 1938. The plebiscite was to be held on March 13, 1938. On March 11 Hitler at first demanded a postponement, threatening military occupation otherwise. The plebiscite was therefore postponed.

Anschluss.—Thereupon Hitler demanded the immediate resignation of the Austrian government, which was to be replaced by National Socialists named by him; only in this case would he be prepared to abstain from invading the country. When Austria had been forced to accept this ultimatum as well, to save its freedom, Hitler gave orders for the military occupation of Austria. Austria protested openly and declared that she had to give in to brute force; Hitler thereupon issued a statement that the Austrian assertion about a German ultimatum had been a complete and badly-invented lie, as Austria had asked him for the entry of German troops.

On March 13, 1938, Hitler ordered the new, National Socialist Austrian government to force President Wilhelm Miklas of Austria to abdicate and to conclude the Anschluss. The new law was passed, and on March 15 Hitler personally proclaimed the Anschluss in Vienna. The new Austrian chief of government, Seyss-Inquart, was made governor, but was at the same time subordinated to a

reich commissar, Josef Bürkel, who had been brought in from Germany.

A few months later the name "Austria" was officially obliterated. The country had lost its historic name, and was divided up into the so-called Danube and Alpine provinces (Gau). At the same time, forced re-armament and economic exploitation were started on a grand scale, but with that the currency and the economic structure of the country were completely destroyed. The men who had led the struggle for Austrian independence as well as the officials who had remained faithful to their duties and the constitution were almost without exception sent to prison or concentration camps.

Persecution of Jews, especially in Vienna, began on a very large scale in Nov. 1938; the plundering was legalized under the name of "Aryanization."

Every open opposition was stamped out, but very soon secret resistance movements began to rise. They were suppressed with bloodshed again and again, and counted thousands of victims. When World War II broke out the Austrians were distributed among various contingents, so that the so-called Ostmark units never contained more than a minority of Austrians, and were never led by Austrian officers.

The Austrian resistance movement both at the front and at home grew steadily throughout the war. It drew its strength from all former political parties, and paid a very heavy toll of lives. The outside world did not hear about Austria or even the Ostmark, as if the country and its people had ceased to exist.

After heavy aerial attacks, especially against Vienna and some other cities, eastern Austria with Vienna was liberated in April 1945, by the Red army, the western parts of the country by the forces of the western Allies. (See WORLD WAR II.)

The universal free parliamentary elections held on Nov. 25, 1945, showed the same relative distribution of political strength as had existed in the country before Hitler's aggression: a majority of the (Catholic) People's party (1.574.537 votes and 85 seats), a Social Democrat party of almost the same strength (1,420,562 votes; 77

seats); and a numerically unimportant Communist group (175,471 votes; 3 seats). A coalition government (8 People's party; 6 Social Democrats; one Communist), under the leadership of the Agrarian, Leopold Figl, administered the country with dexterity and resourcefulness. Dr. Karl Renner was elected president of the second Austrian republic on Dec. 20, 1945, and on Jan. 7, 1946, the new government won diplomatic recognition from the Big Four powers—the United States, U.S.S.R., Great Britain and France. The liberated, but as yet occupied, Austria awaited the promised day of freedom. (See also Allied Control Commission for Austria.)

Automobile Industry

In the automobile industry the decade 1937-46 encompassed the most cataclysmic changes experienced during the 50 or more years of the industry's history. The first year of the decade, 1937, saw an output of passenger cars in the United States, which had been exceeded only once, in 1929, and a production of motor trucks equalled only in 1946, the last year of the decennium.

In the second year of the decade, the industry suffered the most drastic recession in peacetime production ever to occur in a comparable period of time. The 1938 output of passenger cars declined nearly 49% and motor trucks 45% below 1937.

Passenger car production in 1937 was 3,915,887 units and in 1938 was 2,000,985, while motor truck output decreased from 893,085 in 1937 to 488,100 units in 1938.

In 1939, a revival occurred in the demand for new vehicles, raising passenger car output 43% and trucks 45%. The recovery continued in 1940 and the first half of 1941, when the impact of war in Europe and the defense preparations in the United States made it necessary to begin curtailment of production of civilian articles, because of shortages in several raw materials and of the need for plant facilities for armaments production.

Hitler's attack on Poland, Sept. 1, 1939, stimulated the U.S. war department to begin mechanization of the army. Before the end of 1939, 6,188 motor vehicles were delivered to the U.S. army, and to 'Great Britain and France. Hitler's continued successes created feverish rearmament programs in Great Britain and France which stimulated in considerable measure the industrial activity of the United States by placement of large orders for war and industrial articles in 1940. Particularly after Dunkirk, when the German motorized armies had demonstrated the power of blitzkrieg, the U.S. government became sufficiently alarmed over the sinister turn of events to begin a complete

mechanization program for the army. In June 1940, Pres. Roosevelt created the National Defense Advisory committee to expedite the entire rearmament program of the United States and to co-ordinate the purchases and requirements of Great Britain, Canada and other democratic countries with those of the United States. This program, together with the direct purchases by the future allies, resulted in the production and delivery of 53.389 military vehicles in 1940 and 218,880 in 1941.

In addition, several motor vehicle and parts manufacturers accepted orders to produce other war products than military vehicles to the extent to which plant facilities and equipment were usable or adaptable. Nearly all these early projects required redesigning and engineering changes so as to make them suitable for mass-production methods. These alterations and adaptations consumed a great deal of time despite the feverish efforts exerted to speed up preparations and get into production of the finished articles. By Dec. 31, 1940, the U.S. automobile industry had produced and delivered \$23,286,000 in aircraft engines and aircraft parts, \$338,000 in guns, \$17,016,000 in diesel engines for submarines, \$187,000 in ammunition components and \$1,293,000 in other war articles in addition to \$115,863,000 in military vehicles.

A considerable amount of the early war work, especially of aircrast components, was stimulated by the activities of the Automotive Committee for National Desense, which was organized Oct. 25, 1940, by the industry itself to stimulate participation in the national desense program.

In 1941, a number of large war projects requiring new plants and special equipment was undertaken by the industry for the mass production of armoured tanks, aircraft engines, complete aircraft and guns. Some of these new facilities began actual production of finished armaments during the summer of 1941. The output of war products continued gaining momentum during 1941 so that by the end of that year the industry had turned out a cumulative total of \$1,091,137,000. Of this, \$201,619,000 was aircraft, aircraft engines and aircraft subassemblies; \$61,616,000, tanks; \$118,232,000, marine products; \$27,866,000, machine guns and other weapons; \$645,307,000, military vehicles and parts; \$25,008,000, ammunition; and \$11,787,000 miscellaneous war products.

The impact of this growing rearmament program, along with that of the nation as a whole, was such that it became necessary to curtail production of motor vehicles for civilians in order to conserve critical imported materials for reserve stockpiles in event war developments shut off supplies from abroad, such as rubber, tin, chromium and tungsten, and to channel a greater proportion of the iron and steel into war articles. Hence, in July 1941, a schedule of curtailed output of passenger cars was imposed by the U.S. government under its war emergency powers, providing for a tapering off of production so that the average for the year ending Aug. 1, 1942, would be about 50% lower than the 1941 model year. By the end of 1941, the rate of actual production had been reduced to approximately the 50% level.

Full Conversion.—The unexpected attack by Japan on Dec. 7, 1941, brought the United States directly into the war as a fighting ally; within a few weeks U.S. government plans were completed for conversion of the automobile industry to 100% war production. Execution of plans followed with a number of successive steps.

First, normal sales of all new motor vehicles were banned after Jan. 1, 1942. All new or used 1942 models remaining unsold, and those still to be produced, were placed in a so-called "pool" for rationing under government control.

Units

23!

Second, production of passenger cars and light commercial cars was ordered stopped after fabrication and assembly of parts and materials on hand before Feb. 10, 1942. Production of medium-sized trucks (9,000 to 16,000 lb., gross vehicle weight) for civilian use was discontinued by March 31 and heavy trucks (above 16,000 lb., gross vehicle weight) for civilian use by May 31, 1942. Production of essential replacement parts was permitted at the rate of output during the first six months of 1941, which was at record levels. Later this was stepped up to 150% of that base period.

Third, orders for armaments exceeding \$5,000,000,000 in value were placed with the automotive manufacturers for aircraft, aircraft engines, aircraft subassemblies and parts, armoured tanks, machine guns, cannon and other artillery, ammunition, armoured cars, personnel and weapon carriers and other military vehicles, and miscellaneous war products. These orders were in addition to the nearly 5,000,000,000 orders that had been placed with the industry prior to that time.

Fourth, a branch office of the War Production board was established in Detroit to aid manufacturers in that area to convert plants and equipment and to obtain the new facilities required in getting into production, with the minimum of delay.

Anticipating the moves by the U.S. government, leaders of the automotive manufacturing industry organized the Automotive Council for War Production on Dec. 30, 1941, as an organization for co-operative action in producing war materials for the military agencies of the U.S. government and its allies. In a resolution at its first meeting the following pledge was made: "The nation will not lack for one gun, one tank, one engine, that the capacity and ingenuity of this industry's producers can add to the forces of our nation and its friends on all the fighting fronts."

The Automotive Council for War Production undertook to aid manufacturers during the conversion of plants and facilities engaged in peacetime production of automotive products and some war materials, to a 100% capacity basis on war products. Speed was of the essence. Problems were referred to committees of experts chosen from the motor vehicle and parts-manufacturing companies. Information and "know-how" on mass-production methods, time-saving techniques, product improvements, tooling short-cuts and other methods were exchanged at meetings or plant visits where demonstrations could be observed.

Similar methods were used throughout the war in expediting war production.

The staff of the Automotive Council for War Production disseminated the results of the meetings to all other manufacturers in the industry, and in many cases to others outside the industry. Machine tools not needed by any company were reported to the Automotive Council for War Production, and other companies were notified by bulletins of their availability. Purchases or loans were then made directly between companies. Also, tool and die shops reported idle capacity in their establishments to the Automotive Council for War Production, which published a weekly consolidated report, and again direct contacts were established between interested parties. Bulletins were likewise issued giving information on parts which prime contractors wished to subcontract to other manufacturers. The Washington office of the Automotive Council for War Production reported promptly to manufacturers, orders issued by the various war agencies that affected the indus-

Armaments Production.—The effective teamwork of the motor vehicle, parts and tool and die manufacturers

throughout the war years resulted in greater contributions to an earlier end of the war than would have occurred without such co-operation. After closing down all plants producing civilian products for complete conversion to war production on or before Feb. 10, 1942, the industry began the herculean task of tearing up assembly lines, rearranging and relocating usable machinery and equipment, changing and rebuilding all machines which possibly could be utilized in war production, placing orders for 1aw materials and additional machine tools and getting their delivery on schedule, training new and old employees for different types of work, generally requiring greater precision than those in peacetime, and adopting engineering changes in the designs of weapons to make possible their mass production. Progress was at such a pace that by August the rate of operation, measured in dollars, had equalled prewar peak levels. The increase in output of military vehicles and other war production carried on simultaneously with civilian motor vehicle and parts production, together with the output of new government-financed plants built and operated by the industry prior to February, made this record possible. The rate of war production continued climbing rapidly during the following year, after which production began to level off or even decline because of adequate supply. Aircraft production, however, continued climbing.

The motor vehicle and parts industry, with the government-financed plants built and operated by the industry's manufacturers, produced an aggregate of approximately \$29,000,000,000 of war materials, not counting the provision of facilities for the production. It was estimated that the automotive industry produced one-fifth of the total output of war materials turned out by all the metal-fabricating industries of the United States.

Rationing.—As part of the government's general program of conserving all supplies required directly or indirectly for the over-all war effort of the United States, passenger cars, trucks, gasoline and rubber tires and tubes were rationed to persons doing work most essential to the winning of the war.

The stock of new cars and trucks remaining unsold on Jan. 1, 1942, and those produced thereafter were placed in a so-called "pool" and rationed to certain eligible classes.

New passenger cars were rationed, after proof of need, to certain eligible classes: doctors; veterinarians; visiting nurses; ministers; persons needing cars for ambulances, fire-fighting, police work, public health and safety work, U.S. mail service, taxicabs and highway work; executives and workers in war plants, etc.; persons hauling newspapers for wholesale delivery; the American Red Cross and a few other types of essential users.

Motor trucks were likewise rationed to civilian persons who could prove need in connection with transportation of commodities and services classed as most essential to the prosecution of the war. Of course, the military agencies throughout the war provided for their requirements by orders placed with truck manufacturers.

Conservation of the stock pile of natural rubber became imperative. Until synthetic rubber could be improved to the point where it would serve as a satisfactory substitute for the natural product, and until plants and equipment could be built on a scale large enough to supply the huge war demand, the meagre inventory had to be channeled into the most important war uses. Hence, rationing of natural rubber for the production of new tires and recapping of old tires and also the rationing of the new tires and tubes to the most essential motor vehicle users was ordered by the U.S. government. Thanks to the ingenuity

of all whose responsibility it was to direct the creation of a new industry, the supply of synthetic rubber became available in adequate amounts on time to keep the passenger cars, trucks and busses rolling at the limited wartime mileages considered necessary.

As the juggernaut of war gathered momentum, gasoline for military vehicles, combat tanks and planes, and fuel oil for warships and transports were needed in ever greater quantities. Vast as was the capacity of the American petroleum refining industry, it, nevertheless, became necessary to curtail the use of this commodity by motor vehicle users. Rationing for civilian users was put into effect in the 17 eastern states on May 15, 1942, and in the remainder of the United States on Dec. 2, 1942. Sufficient gasoline was allowed each owner to continue his necessary mileage provided he joined in a "driving club." This was an arrangement among car owners to take turns in using their respective cars in driving to and from work, or in driving children to and from school. Surveys of war plants indicated that 69% of workers used automobiles in getting to work. Public transportation agencies could not take care of transportation requirements of war workers. Motor truck and bus owners, under the spur of the Office of Defense Transportation, were required to eliminate unnecessary mileage by forming joint delivery schedules, avoiding duplication of routes, loading to practicable capacity and reducing frequency of deliveries, or by utilizing other gasoline conservation plans approved by that wartime transportation authority.

Soon after the United States entered the war, the government adopted a wage and price stabilization program which included a so-called "ceiling" on prices of new passenger cars, trucks, busses, replacement parts, accessories, repairing of vehicles, gasoline, transportation rates and other automotive categories, based on maximum prices charged during a previous period of time. Adjustments of prices were provided for in special cases, and, in the instance of new vehicles sold from the "pool," a monthly price increment of 1% was allowed to cover storage and maintenance costs. (See also PRICE ADMINISTRATION, OFFICE OF; RATIONING.)

Motor Vehicle Registrations.—It was fortunate indeed that the consumer inventory of motor vehicles, particularly of passenger cars, consisted of a relatively high proportion of new vehicles produced in years just prior to the entry of the United States into the war, thereby enabling the industry to concentrate fully on production of war materials throughout the war period. It became necessary to resume production of only a small number of civilian trucks and busses during the war period to take care of urgent transportation of war products and of war workers. The number of passenger cars in use at the beginning of the war was 27,600,000, after eliminating cars scrapped from the registration total of 29,524,000. It was estimated by Charles L. Dearing of the Brookings institution that a minimum of 20,000,000 passenger cars was required in the United States in order to maintain an efficiently-functioning economy. Surveys of war plants later indicated that more than two-thirds of war plant workers depended on automobiles for transportation between home and factory. In some instances, 80% to 90% rode to work in automobiles, participating in "share ride clubs" where each rider took his turn in furnishing the automobile, to conserve gasoline and rubber tires as well as the car.

Although the total number of motor vehicles in use dwindled with the progress of the war, part of the de-

cline in registration totals was explained by the storing of passenger cars without registering them, until gasoline supply or rubber tires would again become readily available at or toward the end of the war. The re-registration of automobiles put in storage at the beginning of the war accounted for the smallness of the decrease in 1944, and the slight increase in 1945 and also for most of the large gain shown in 1946, as indicated in Table II.

The lowest registration point reached during the war, in 1944, with 25.572,842 passenger cars, was still considerably above the minimum of 20,000,000 set by the Brookings institution as the critical point. Automobile owners during the war learned that they could prolong the life of their cars by better maintenance and more careful driving. The rationing of gasoline reduced greatly the annual mileage driven per average car, by perhaps 50%. Instead of an average of 9,000 mi. annually in prewar years, the per car average in 1943, 1944 and first half of 1945 was approximately 5,500 mi. per year.

Motor truck registrations at the lowest point (1943) during the war showed a decline of only 400,000 units, or 8%, below the prewar peak. The tremendous demand for all forms of transportation to haul industrial, agricultural and war products to where they were needed, necessitated keeping on the highways and streets every vehicle that could possibly be reconditioned or repaired. Some passenger cars were converted into goods-carrying vehicles, and a limited production of new civilian trucks was permitted. By means of gasoline rationing, the use of trucks in hauling certain types of commodities was reduced. Other conservation measures also contributed to the maintenance of nearly all trucks in operation at the beginning of the war in active service throughout the war years.

Wartime Highway Transport.—World War II demonstrated the vital importance of truck transportation in an economy of mass production with its highly specialized manufacturing processes. Raw materials, semi-finished products and finished parts had to be hauled, often great distances, to factories using them in further processing or assembly into finished articles, and then the final distribution to ultimate consumers. Delivery schedules had to be maintained all along the line to avoid disruptions affecting large segments of the economy.

The speed and flexibility of motor trucks did yeoman service in keeping war production lines in operation. Trucks were dispatched to carry the emergency products on over-night trips that would have required several days by the normal transportation agencies. On other occasions emergency products were hauled by truck over distances of 1,000 mi. or more to keep desperately needed armaments moving out of factories on their way to the fighting fronts.

Another field of special transportation service where the truck demonstrated efficiency was in the transportation

of semi-finished parts or subassemblies produced in one plant but required in another plant, 15, 50 or 100 mi. distant, for assembly into a finished end-product as part of the mass-production process. Small plants often located in towns not readily accessible by other means of transportation, and at times not accessible at all by other transportation methods, were utilized as subcontractors by large and small prime contractors in the production of one or more parts of a gun, bomber or other armament; these plants could draw upon local skilled labour with adequate housing and local means of going to and from work. This extension of the assembly line beyond the one factory was not peculiar to war production, although it was used more intensively during the war period than in peacetime. It had been used before the war in a great many factories employing the progressive manufacturing techniques originally developed by the automobile-manufacturing industry.

The day-in and day-out job of hauling by truck, aside from the above-described services, still continued to be the usual trucking of commodities from farm to city, from factory, store or farm to railroad station or pier on the water routes, and in opposite directions; from home to home, and countless other combinations in the movement of goods.

These vital services of truck operators were carried on despite handicaps resulting from the war. Because Japan cut off the normal supply of rubber, conservation of rubber and rubber tires and rubber inner tubes became imperative. Because gasoline was consumed in greater and greater quantities by the engines of war, it became necessary to conserve the supply of motor fuel. Truck operators, consequently, were called on to co-operate in the saving of rubber and gasoline by reducing the frequency of deliveries of less essential articles of common use, by loading vehicles to practicable capacity, by joining shipping pools to reduce or eliminate duplication of routes, and by other methods.

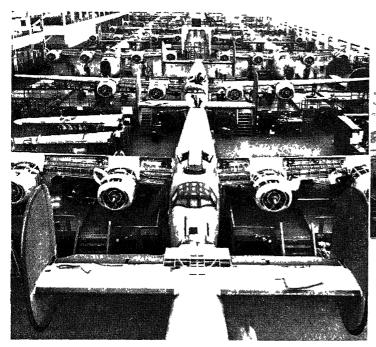

Estimates by the U.S. Public Roads administration indicated that the aggregate mileage driven by motor truck operators declined somewhat during the war years, because of mileage conservation measures. The average load, however, increased considerably, so that total ton-mileages hauled annually during the war were approximately the same as in prewar years, combining all types of trucking operations. The for-hire truckers hauled tonnages aggregating 75% to 90% above the totals moved during the prewar period of 1938 to 1940.

In Combat.—The vital services of motor trucks in combat areas was graphically described in a bulletin issued by the Office of the Chief of Transportation, Army Service Forces, European Theatre of Operations, of the U.S. army:

In the actual invasion, trucks played a major role. Transportation Corps drivers were depended on to get the supplies through, and storming from the maws of LSTs (Landing Ship, Tanks), wound their sloshing way through water and sand to gain the beachheads. After the initial assault in which the Germans were driven back from their fortified pill boxes and gun emplacements, an even heavier task confronted the truck companies.

More troop ships landing demanded more supplies and a never-ending ribbon of motorized equipment worked on an around-the-clock schedule. A gap from the front lines to the beaches had to be bridged, and only motor vehicles could do the job. There were no railroads to bear part of the burden. Everything had to be brought up by trucks, and swiftly.

Reconversion.—In anticipation of the war's end, the contract termination committee of the Automotive Council for War Production began making plans for the day when Germany and Japan would capitulate and war contracts would be cancelled en masse. The most expeditious

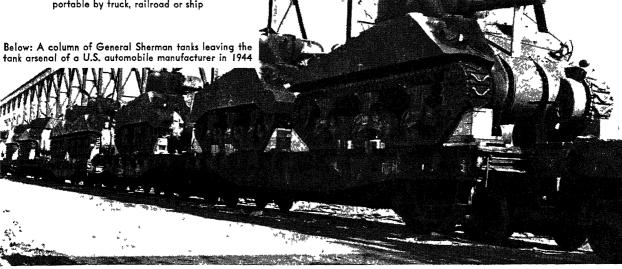

Above: Anti-aircraft guns (40-mm.) made by a U.S. automobile manufacturer, in operation aboard a carrier of the U.S. fleet

Left: B-24 Liberators on the production line at Willow Run, Mich., huge bomber plant built by Henry Ford and completed in 1942

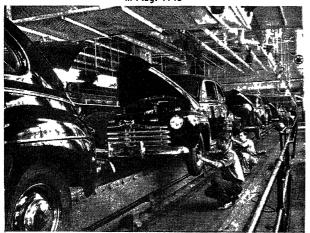

methods for handling the deluge of paper work made necessary by this wholesale cancellation of war contracts was developed in co-operation with the U.S. government's contract termination agencies during the winter and spring of 1945. Plans were made for the prompt removal of government-owned machine tools, equipment and materials from the industry's own plants and the removal of the industry's equipment from the government-owned war plants, so as not to disturb any production activity that might be necessary to continue beyond the day of the cease-fire order.

Individual manufacturers made plans for the acquisition of new equipment needed to replace the peacetime machinery worn out by the war work or sold to other manufacturers. This pre-reconversion planning enabled manufacturers later to make the transition from war production to their respective peacetime activity in the least possible time, and much more smoothly than if this foresight had not been exercised.

Shortly after the German capitulation in May 1945, the government cancelled some of the war contracts held by former passenger-car manufacturers, thereby making possible the resumption of passenger-car production on a small scale while continuing the production of the war products required for the defeat of Japan. The War Production board, after consultation with industry representatives, allocated a quota of 241,916 passenger cars to manufacturers in proportion to the prewar base period output, but modified to provide a minimum practical schedule for the smaller manufacturers. This quota was for the period ending Dec. 31, 1945. Another quota of 449,102 cars was allocated for the three months ending March 31, 1946, taking into account the advantages allowed smaller companies for minimum operating rates during the earlier period. The total allotment of cars was limited by the amount of steel and other materials available above those required for the continuing production of war articles and other civilian products.

The ban on production of civilian passenger cars was removed July 1, 1945, by the War Production board. Several hundred cars had been produced by the time Japan capitulated. After the defeat of Japan, manufacturers encountered the expected deluge of contract cancellations. But, because of the thorough pre-conversion planning, the huge volume of paper work required and the physical

Ford cars starting to roll off an assembly line in Detroit, Mich., in Aug. 1945

task of removing and rearranging machinery and reconstructing assembly lines proceeded with anticipated celerity.

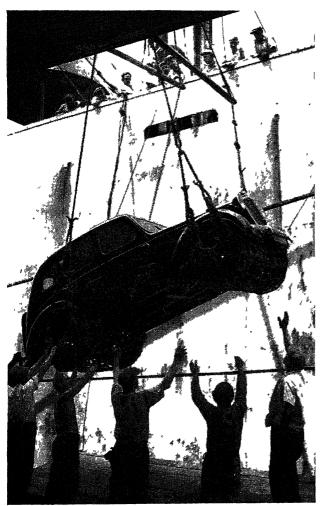

Passenger-car production schedules reported to the War Production board after the end of World War II indicated that manufacturers expected to produce a total of 500,000 passenger cars by Dec. 31, 1945; but only 83,792 were actually turned out. The manufacturers had expected to produce about 2,800,000 by June 30, 1946, but only 725,824 were actually constructed. The reasons for this disappointing development were ascribed to the shortages of various materials such as glass, textiles, pig iron and steel, and lack of an adequate flow of parts and components for the cars such as transmissions, gears, wheels, bearings, because of strikes in supplier plants and work stoppages in passenger-car manufacturing and assembly plants. The shortages of materials were greatly aggravated by the general strikes in steel manufacturing, coal mining and railroad transportation and to a limited degree by the strikes in electric utilities plants.

Reconversion of the truck-manufacturing and the automotive-parts plants, except those building passenger-car bodies, was a simple task compared to that of the passenger-car manufacturing branch of the industry. Physical alteration of the facilities used in producing transport and combat vehicles in the truck factories was negligible by comparison. The problems concerned principally the termination and settlement for inventories of materials and work in process that could not be used in production of civilian trucks.

Civilian truck production had the advantage of a running start when the Japanese war ended because the War Production board had earlier in the year allocated a large civilian program to the truck makers, accompanied by allocations of necessary materials. The actual production of civilian trucks during the last four months of 1945 was handicapped by shortages of materials and components such as axles, gears and transmissions caused largely by strikes in supplier plants. The rate of output during the latter part of the year was estimated at only 50% of actual practical capacity. Despite this, a total of 313,643 civilian trucks were built during the year in addition to the 354,-935 military vehicles produced, mostly prior to the war's end.

As the turbulent decade drew to a close, the automobile industry was still struggling to reach prewar levels of production, but the year 1945 produced only an estimated 2,170,000 passenger cars. Unlike passenger-car manufacturing, truck makers turned out a new record total of 950,000 trucks for civilian use.

Golden Jubilee.-The final year of the decade, 1946, marked the 50th anniversary of the beginning of the automobile industry, during which more than 91,000,000 vehicles had been produced in the United States. This event was fittingly celebrated by a golden jubilee in Detroit. The events, among others, considered significant in the development of the automobile were: March 6, 1896-Charles B. King was the first to drive his horseless carriage on the streets of Detroit; April 2, 1896-Barnum and Bailey's circus exhibited a Duryea motor wagon as the stellar attraction of its parade; May 30, 1896-A horseless carriage race in New York city was sponsored by John B. Walker; June 4, 1896-Henry Ford successfully drove in his first automobile in Detroit; Sept. 7-11, 1896—World's first motor vehicle track race at Narragansett park, under auspices of Rhode Island state fair; Sept. 12, 1896-1000 mi. endurance race for automobiles from Paris to Marseilles.

First British postwar automobile sent overseas, an Austin four-door sedan, being lowered onto a New York pier on its arrival from Liverpool in July 1945. The delivery marked a reopening of peacetime trade between Great Britain and the U.S.

A parade of more than 200 of the oldest vehicles still in existence, a pageant of early Detroit history, and a dinner honouring living pioneers, served to commemorate the event.

In England, the motor industry celebrated the 50th anniversary of the "Locomotives on Highway Act of 1896" which made the driving of motor vehicles up to 12 mi. per hour legal. An act passed in 1878 had required that a vehicle be preceded at 20 yd. distance by a person on foot. Although no British motor vehicles were produced at the time, the Act of 1896 did encourage pioneers to enter the field, in competition with imported German and French automobiles.

British Production.—With the war striking both the United Kingdom and Canada immediately after Hitler's invasion of Poland, the impact of war production affected the output of civilian passenger cars and trucks earlier than in the United States, especially in England. Passenger-car production in England was practically eliminated in 1940, but production of transport vehicles was increased considerably in that year, establishing a new high output of 133,700 units, exclusive of armoured trucks. The output of motor trucks continued at nearly this record level throughout the war period.

Output of civilian motor vehicles was resumed in England in 1944, when a total of 2,100 passenger cars and

130,844 motor trucks were produced. In 1945, 16,938 passenger cars and 122,467 motor trucks were produced. In the first 7 months of 1946, 99,534 passenger cars and 79,499 motor trucks were produced. Of the latter totals, 46,808 passenger cars and 26,249 trucks were exported, representing 47% of the former and 33% of the latter. This compared with the exports for the 12 months ending Sept. 30, 1938 of 22% for passenger cars and 15% for trucks.

Passenger cars in use toward the end of 1938 were 1,819,-376; motor trucks 483,865; and hackneys 83,977. Registrations indicated a total of 1,473,742 passenger cars, 478,-056 motor trucks or goods vehicles, and 104,401 hackneys in use as of Nov. 30, 1945, according to the Society of

Motor Manufacturers and Traders, Ltd. At the end of the war, there had occurred a decrease of 345,637 passenger cars and 5,809 goods-carrying vehicles. But the total number of hackneys (busses and taxicabs) had increased by 20,424.

Canada.—In Canada, production of passenger cars for civilian use was discontinued during the spring of 1942, although operations had continued on a reduced scale up to that time. Production of motor trucks for civilian use continued on a greatly reduced basis during the war period, with only 4,088 trucks turned out in 1943 and 9,113 trucks in 1944.

The use of passenger cars in Canada reached a peak of 1,280,000 at the end of 1941. The decline during the war

was relatively small, showing a loss of only 120,000 units. Truck use, on the other hand, continued increasing throughout the war period, from 253,000 in 1940 to 321,000 at the end of 1945.

The output of military vehicles by motor vehicle plants in Canada was reported by the Dominion Bureau of Statistics as 762,395 for the years 1940 to 1946 inclusive. (See also Accidents; Business Review; Disasters; Insurance; Motor Transportation; Petroleum; Roads and Highways.)

Automobile Racing

Ten years of auto racing during the period 1937–46 could not be considered an accurate yardstick of the acceptance or achievements in the sport because at least half of these years saw most events requiring rubber tires and gasoline cancelled in deference to war shortages.

The decade opened auspiciously with a world land speed mark being broken by Captain George E. T. Eyston of England over a measured mile on the Bonneville Salt

John Cobb speeding over the course of Bonneville Salt Flats, Utah, Aug. 23, 1939, when he broke the world's land speed record, driving at 368.85 m.p.h.

Flats in Utah, U.S.A. Captain Eyston drove his "Thunderbolt" at an average speed of 911.42 m.p.h.

Again in 1938, Captain Eyston was the outstanding figure in auto racing. Eyston whizzed through a measured mile at 357.5 m.p.h. in September over the Bonneville Salt Flats. He thus erased the mark of 350.2 m.p.h. established 24 hours previously by John R. Cobb, a London fur broker.

Cobb, however, made another successful assault upon the world's land speed record in 1939. He streaked through a measured mile on the Bonneville Salt Flats on Aug. 23, at 368.85 m.p.h. By travelling more than six miles a minute Cobb thus regained the world's straight-away speed throne which he had held the previous year for a brief span of 24 hours. He drove a 2,600 horse-power 24-cylinder aluminum "Railton Red Lion."

Oblivious of gathering war clouds, a syndicate of wealthy Americans constructed and opened Roosevelt raceway in Westbury, Long Island, N.Y., in 1937, and revived the Vanderbilt Cup race, which was won by a German driver, Bernd Rosemeyer. He drove his rear-motor "Auto Union" to victory over his English rival, Richard Seaman. With the advent of World War II the horse replaced the automobile, and Roosevelt raceway was transformed into a harness racing track.

Midget auto racing continued to prosper, and more than 50 tracks were active during the early part of the decade, six of them forming an eastern circuit and operating under A.A.A. sanction.

The annual 500-mile Indianapolis Speedway classic continued to be the principal U.S. automobile racing event until it was discontinued in 1942 after U.S. entrance into World War II. The 1937 event was won by Wilbur Shaw of Indianapolis in 4 hr., 24 min., 7.8 sec.—an average of 113.58 m.p.h. Floyd Roberts of California won the 1938 race at a record average speed of 117.20 m.p.h., and Shaw repeated his 1937 performance by taking first place in 1939 at an average speed of 115.035 m.p.h. In the latter race Roberts was killed-the Speedway's first fatal accident after 1935. By capturing first place again in 1940, at an average of 114.277 m.p.h., Shaw became the first man in the 28-year history of the event to win two years in succession. The 1941 race was noteworthy in that two drivers piloted the first-place car-Mauri Rose of Indianapolis, Ind., and Floyd Davis of Springfield, Ill., who maintained an average speed of 115.117 m.p.h.

The war years brought an abrupt halt to any further auto racing until 1946, when the Indianapolis classic on May 30 was won by George Robson in 4 hr., 21 min., 16.70 sec., maintaining an average speed of 114.820 m.p.h.

(T. J. D.)

Avery, Sewell Lee

Avery (1874-), U.S. business executive, was born Nov. 4, 1874, in Saginaw, Mich. He was graduated from the University of Michigan law school in 1894. He became eastern sales manager of the U.S. Gypsum company in 1901 and president of the organization four years later. In 1931, he also became director of Montgomery Ward & Company. A militant opponent of the New Deal, he attained national prominence in 1944 when he refused to obey orders of President Roosevelt and the War Labor board in a labour dispute, and the army took over possession of the Montgomery Ward plant. At the time, Avery refused to leave his office and two soldiers had to carry him out bodily.

Late in Dec. 1944, Avery again defied President Roosevelt and the WLB and a series of strikes swept the Ward

plants and stores; the army again seized the company's plants in Chicago and in six other cities. Roosevelt declared that the company would not be allowed to set aside government wartime policies "just because Mr. Sewell Avery does not approve of the government's procedure for handling labour disputes." Avery replied that "Ward's cannot in good citizenship accept or obey the commands of those who have no legal power to give them." On Jan. 27, 1945, Avery won partial vindication when a federal district judge in Chicago ruled that government seizure of the Ward plant was illegal. On April 27, 1945, Avery was re-elected chairman of Montgomery Ward.

Aviation, Civil

The rapid shift from peace to wartime operations, the fulfilment of seemingly impossible demands of a world at war, and reconversion to meet peacetime needs—these were the main chapters in the story of civil aviation from 1937 through 1946.

By 1937, civil aviation was already well established. Extensive services had been inaugurated, and except for a gap between Manila and the continent of Asia, a traveller could circle the globe by scheduled air transport. Technical progress had resulted in such developments as the NACA (National Advisory Committee for Aeronautics) cowl, the cantilever wing and high octane gasoline. That year saw the appearance of aircraft which were still doing yeoman service in 1946.

Despite its progress, aviation was a youngster beset with growing pains. The lack of navigation aids confined transport operations in a large part of the world to daylight hours and good weather. Air service across the Atlantic was limited to infrequent zeppelin trips. Many of the technical advances were still in an experimental stage; others, while practicable, had not attained general use. Notwithstanding its tremendous strides, civil aviation still had not attained its greatest development.

Chronology of Scheduled Air Transport.—In 1937, Imperial Airways, a British company, vied with Pan American Airways (P.A.A.), sole United States international carrier, for honours as the world's largest air line. Imperial, connecting England with many of its possessions and the members of the commonwealth, operated to Europe, South Africa, India, Hong Kong, and through connections with Quantas Empire Airways, an Australian company, linked Great Britain with Australia. Pan American conducted services between the United States and the Latin Americas, Hawaii, the Philippines and local services within Alaska.

Also operating long-range international services were Air France, K.L.M. (Royal Dutch Airlines) and the German companies, Deutsche Lufthansa and Deutsche Zeppelin Reederei. Air France operated to points in Europe, Africa, Asia and South America. The major route of K.L.M. outside Europe was to the Netherlands East Indies. Lufthansa flew the South Atlantic to Brazil, and Deutsche Zeppelin conducted dirigible service across the South and North Atlantic.

In domestic operations, the U.S. led the world, with a

system having 31,084 unduplicated route miles and carrying an average of 3,400 passengers each day. Canada, lacking a transcontinental route, had numerous north-south services connecting the southern portions of the country with the isolated north. In Latin-America, companies owned by nationals were appearing, but most services were rendered by air lines controlled by foreigners, with Germany extremely active.

In Europe, virtually every nation had one or more air lines, usually government-controlled. Internal services were, on the whole, incidental to international operations; however, domestic services did exist. England had some 17 transport companies. Russia, with two state air transport administrations, G.U.G.V.F. (Aeroflot), and G.U.S.M.P., reported extensive services throughout the U.S.S.R., including routes in the Arctic and Iar east. But Germany was generally credited with the most complete internal services.

Australia had approximately 14 companies connecting the principal cities; in Asia, China had three—China National Aviation, jointly owned by the Chinese government and Pan American; Eurasia, controlled by German interests; and Southwest Aviation corporation, entirely owned by Chinese.

During 1937, plans for North Atlantic service with heavier-than-air craft began to take shape when Pan American, Imperial, Air France and Lufthansa started surveys and P.A.A. and Imperial began service between the U.S. and Bermuda. P.A.A. inaugurated a Manila-Hong Kong service, and by extending service to Paraguay, linked by air all capitals of the Latin American republics. The formation of Trans-Canada Airlines, controlled by the government, marked the first step toward the 3,000-mile Canadian transcontinental service.

Friction between Russia and Germany caused dissolution of a joint company which had operated Moscow to Berlin after 1921. However, after the Russo-German nonaggression pact in 1939, service between Moscow and Berlin was resumed by Aeroflot and Lusthansa, continuing until June 1941. On May 6, 1937, the German zeppelin "Hindenburg" burned while mooring at Lakehurst, N.J., after an ocean crossing, killing many aboard. Although Germany planned to convert the "Hindenburg's" sister ship from hydrogen to noninflammable helium, the refusal of the U.S., the sole source of helium, to release any of the gas caused abandonment of the Atlantic service.

Expansion of both domestic and international air services continued in 1938. International route extensions included the linking of Brisbane and Sidney on the London-Australia route and the opening of Batavia to Sidney service by Royal Dutch Indies Airlines, giving the Netherlands an Amsterdam-Australia route. Air France extended to Hong Kong, and Lufthansa began service to the middle east. The Canadian transcontinental route came nearer to realization when Trans-Canada inaugurated daily mail service between Vancouver and Montreal.

In 1939 expansion resulted both from years of planning and wartime contraction. During the summer the long-awaited North Atlantic route became a reality when Pan American inaugurated service between the U.S. and Europe via the Azores and via

The outbreak of World War II caused suspension of numerous services of European carriers. Many were soon revived, but some, such as Lufthansa's South Atlantic operation, were permanently suspended, and others, such as Imperial's North Atlantic service, remained inoperative for considerable lengths of time. Typifying conditions in the warring nations was the British government's assumption of complete direction of air transportation and elimination of nonessential services, leaving only the empire life lines and five railroad-controlled domestic companies.

In addition to the North Atlantic operation, 1939 witnessed other expansion. Trans-Canada began service between Vancouver and Moncton, completing the transcontinental route. The privately-owned Canadian Pacific Railway entered the aviation field, and by 1942 had merged into one organization, Canadian Pacific Airlines, all important north-south feeder routes in Canada. In December, Lati, an Italian government-controlled company, inaugurated Atlantic service to Brazil, an operation that continued until Brazil denied gasoline supplies after the U.S. entered the war.

During 1940, Pan American established a regular San Francisco-New Zealand service, began nonstop flights to South America and operation of the inland cut-off across Brazil, which reduced flying time between New York and Buenos Aires to three and one-half days, and inaugurated regular summer service between Alaska and the U.S. The latter supplied an unbroken route extending from Alaska to Argentina. P.A.A. also continued its important Atlantic service, but the U.S. Neutrality act necessitated ending trips outside the war zone. A second U.S. transatlantic service became assured when American Export Airlines, a new company, was certificated. Imperial and British Airways were merged into the government-owned British Overseas Airways corporation (B.O.A.C.), which undertook operation of all British international services.

The fall of France and the entrance of Italy into the war caused radical changes in the air transport picture. Air France fell into obscurity. K.L.M., most of its equipment destroyed, flew what was left to England and continued operations, maintaining its East Indies service with trips terminating at Palestine. To preserve the empire life line to the east, B.O.A.C. inaugurated flying boat service via Lisbon, Portugal to Lagos, in west Africa, where a connection was made with the established routes across Africa to Egypt and the east. This operation was supplemented the following year by a Pan American route across central Africa, established to supply the British forces in Egypt.

Lufthansa took over services in the occupied countries and continued flights to Lisbon, where, until the end of the war in Europe, its planes landed at the same field as those of the United Nations. Sweden, the only country outside the axis orbit left with extensive European services, operated intermittently to Austria, England, Germany, Hungary and the U.S.S.R.

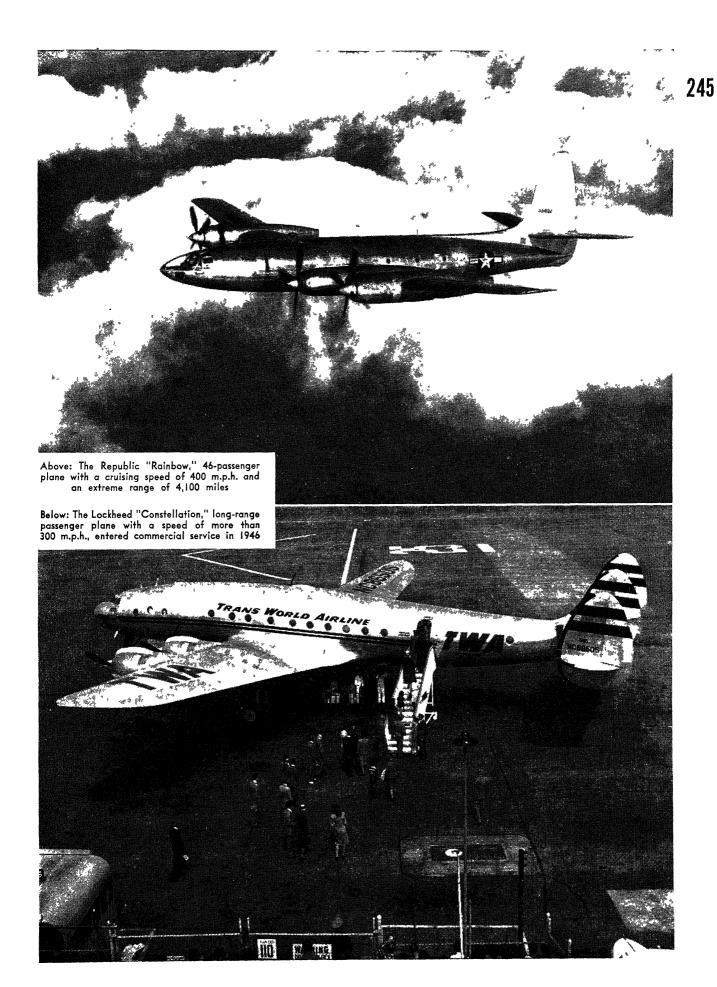

In the far east the Chinese Central government, involved in the war with Japan, took over Eurasia, subsequently called China Air Transport; and Hamiata, a joint Sino-Russian company organized in Dec. 1939, operated limited service from Hami, Sinkiang, to Alma Ata, where it connected with Aeroflot.

England's Atlantic passenger service was finally established in 1941 with routes serving military purposes between England and the U.S. via Africa, and between England and Canada, via Newfoundland. The latter service, undertaken by B.O.A.C. as an adjunct of the bomber ferrying service pioneered the preceding year by the British ministry of aircraft production and Canadian Pacific Airlines, served to return ferry pilots from England to Canada. This operation marked the first service on a year-round basis over the so-called "summer route," which only a few years before was considered impossible during winter months.

The Japanese attack on Pearl Harbor confronted U.S. air lines with their greatest test. Despite the loss of aircraft and personnel to the armed forces and the undertaking of extensive military operations under contract, the domestic air lines, by elimination of nonessential traffic stops and increased efficiency, were able to maintain their civilian services. Operations of the domestic carriers for the following year saw mail and cargo ton-miles almost doubling, and passenger miles declining only slightly.

Entry of the U.S. into the war precipitated the elimination in Brazil of Sindicato Condor. This completed efforts begun several years before to expel German-controlled air lines from South America and to replace their services by those of U.S. or national companies.

The war further disrupted international routes in 1941 and 1942. Pan American's commercial Pacific services fell victim; Dutch services in the East Indies ceased, and Dutch aviation centred around its Caribbean services and contract operations for B.O.A.C. from the British Isles

to Lisbon. British services to the far east ended at Calcutta, India, with the New Zealand-Australia route cut. China National Aviation pioneered the "Hump" route over the Himalayas to India to preserve China's main communication with the Allied Nations.

In 1943, U.S. air lines inaugurated daily commercial all-cargo flights between New York-Los Angeles and New York-San Francisco, the first transcontinental service of this type. Although cargo flights between some points had begun as early as 1940, and four U.S. air lines had formed a joint company to study cargo carriage in 1941, this type of service remained a minor part of the business of the scheduled air lines.

During 1943, 1944 and part of 1945, most air transport throughout the world concentrated on the war efforts of the various countries, operating directly for the armed forces or conducting civilian services under military priorities. With the ending of World War II the contribution of these services to victory became fully known.

With the conclusion, early in 1945, of the major part of the direct war operations for the army and navy, it was revealed that U.S. air lines in those operations had flown a distance exceeding 26,000 trips around the equator, in services extending to all parts of the world. In addition to these spectacular operations, the air lines had trained personnel, and maintained and modified aircraft for the armed forces. Also revealed were the heroic stories of the regular trips of British and U.S. pilots across Africa, forming a vital link with the British forces in Egypt; of the 1,200 trips of B.O.A.C. over axis areas between

The Boeing Clipper, giant transoceanic passenger plane which began scheduled flights from the U.S. to Europe and the orient on June 28, 1939. Civilian service was interrupted by World War II when the Clippers were enlisted as military transports

London and Stockholm, Sweden; in an effort to maintain the supply of vital ball bearings for the aircraft manufacturing industry; and of the 3,523-mile over-water flights of the Australian airmen between that continent and Ceylon, relinking the empire route cut by the Japanese.

No account of wartime transport operations, however, would be complete without mention of the transport services of the armed forces. Although military operations, their effect on civil transport, and the part played in their conduct by personnel of civilian companies linked them inextricably with civil aviation. Starting in 1942, the U.S. army's air transport command (q.v.) developed into the largest air line operation ever known. By the end of the war, the ATC had a fleet of 2,789 modern transport aircraft operating to every part of the world. Between July 1942 and V-J day, 7,000,000,000 passenger miles, 2,333,-000,000 ton miles, and 900,000,000 plane miles were flown. Also conducting widespread operations was the U.S. naval air transport service, which developed into a system utilizing 435 planes and, at its peak, having more than 75,000 miles of routes. The British R.A.F. transport command accomplished similar feats in its world-wide operations.

The liberation of important areas and approaching victory made possible re-establishment in 1944 of some commercial routes which had been inoperative after the early days of the war. Among these was the British London-Paris service, the "blue ribbon" route of prewar days.

Not until 1945, however, did the widespread resumption of commercial operations occur. Although service was limited, routes between the major European cities were reestablished. In the field of long-range operations, B.O.A.C. resumed England-Australia service, and in conjunction with South African Airways, began operation of an England-South African route. K.L.M. resumed service to Batavia for the Netherlands government. During the year,

Trans-Canada for the first time began carrying paying passengers over its Atlantic route, begun in 1943 for the government as a mail and cargo operation.

In the United States, consideration of proposed new routes deferred during the war was resumed, and three U.S. air lines (Pan American, T.W.A. and American Overseas, successor to American Export and controlled by American Airlines) were awarded Atlantic routes extending as far as U.S.S.R. and India, with service to be inaugurated as soon as conditions permitted. These authorizations marked the large-scale entry of U.S. domestic air carriers into the international field. Important additions were made to the domestic network. With route mileage increased to approximately 67,000 miles, it was estimated that 82% of the urban population lived within a 25-mi. radius of the certificated routes in 1945. In October, the elimination of the system of military priorities, in effect from 1942, was a milestone in the return to peacetime operations.

The year 1946 was one of great development. By late fall eight air lines, American Overseas, T.W.A., Pan American, B.O.A.C., Air France, K.L.M., Trans-Canada, Danish Airlines (D.D.L.) and Swedish Intercontinental Airlines (S.I.L.A.), were operating an average of more than eight round trips a day across the North Atlantic.

In western Europe, routes as extensive as the prewar network were in operation, and only the lack of equipment and gasoline prevented services from exceeding those of 1939. Many changes, however, had occurred. Gone was the Lufthansa, with Germany banned from all aviation activity, and in Italy hopes for scheduled transport rested in two companies, one controlled by Italy and B.O.A.C., and the other by Italy and T.W.A. In eastern Europe, many of the prewar companies had also disappeared, to be replaced by companies controlled by the national governments alone, or jointly with the U.S.S.R. Even by the summer of 1946, services between eastern and western Europe had not begun again on a prewar scale, though Prague and Warsaw had numerous connections. Aeroflot, however, had expanded its prewar European services by connecting Moscow with the eastern European capitals and Germany.

B.O.A.C. had not only resumed all prewar intercontinental services, but was operating additional ones, and British South American Airways, a new company, was operating a priority service to Latin America. Air France, with its international routes restored, and Panair do Brazil, a Brazilian company of the Pan American system and a newcomer to the transatlantic field, were competing with B.S.A.A. across the South Atlantic. In the Pacific, Pan American resumed its services and Australian National Airways began service for the Australian government from Australia to Canada pending the completion of plans for a joint British, Australian and New Zealand company for a transpacific route.

Many South American countries were fostering national companies, and in 1946 two Colombian air lines were authorized to operate to the U.S. Trans-Canada was offering not only transcontinental and transatlantic service, but also frequent flights to seven U.S. cities including New York city, Chicago, Ill., and Seattle, Wash.

The immediate postwar U.S. international picture was completed when Pan American was authorized to extend its Pacific services to India to connect with its Atlantic route, giving it a

service circling the globe, and was certificated to operate another route across the South Atlantic to Capetown. A second round-the-world route was set up by extending Trans-World Airline's European route to Shanghai, and Northwest Airlines' services from the U.S. to the same point via Alaska. Still other extensions gave Braniff Airways a route to Buenos Aires and extended several other operators to the Caribbean area. But despite considerable progress, the inauguration of service over many portions of these routes was still distant at the end of 1946.

The U.S. domestic air lines, freed from wartime controls and with an ever-increasing supply of equipment, expanded services in all categories. The number of trips between such cities as New York and Washington, D.C., increased to more than 57 round trips daily, and transcontinental schedules, making only a refueling stop en route, were inaugurated. Strenuous efforts were being devoted to air cargo, with slashes in rates, simplification of rate structure, institution of contract services and acquisition of specially-equipped cargo aircraft.

The postwar pattern of the U.S. domestic system also began to emerge when several small companies were authorized to conduct local and feeder services, linking the less-thickly populated communities with each other and with the major trunk lines. This type of service had been pioneered by All American Aviation, Inc., in 1940, when it began a mail "pickup" feeder service. Intrastate lines, operating scheduled services wholly within a single state, began for the first time to appear in numbers.

Nonscheduled and Miscellaneous Services.—Despite the increases in scheduled operations before World War II, nonscheduled, charter, taxi, sightseeing and miscellaneous services in many countries employed a substantial portion of all civil pilots, mechanics and aircraft. During the war these services were greatly curtailed or eliminated, but they again played a big part in the expansion of civil aviation after the war.

The unprecedented expansion of nonscheduled commercial air carrier postwar service in the United States comprised one of the major events for the ten-year period in that country. Pioneered by veterans with priority to purchase surplus military transport planes, these operations developed the most extensive civilian air cargo business ever seen, transporting a wide variety of commodities, many of which had never before moved in volume by air. In addition to cargo, the "nonscheds" conducted extensive passenger operations, graphically portrayed by the estimate that during the resort season of 1945-46, more passengers per day left La Guardia field, N.Y. for Miami and Palm Beach, Fla., by nonscheduled carriers than by the scheduled lines. With equipment ranging from light single-engine planes to four-engine DC-4s, these operators covered the U.S., flew to South America and across both the Atlantic and the Pacific. One of them flew a load of 50,000 eggs from the United States to Warsaw; another flew 306 employees of a Philippine government agency, plus some 3 tons of equipment, from California to the Philippines.

In the United Kingdom, nationalization of the scheduled services, left nonscheduled, charter and miscellaneous services the only fields open to private enterprise. In Sept. 1946, more than 50 charter services existed in the United

Interior of an Avro York, transport version of the Lancaster bomber, accommodating 12 to 56 passengers and in service with the British Overseas Airways corporation. B.O.A.C. routes connected Grect Britain with points in Europe, Africa, Asia and Australia

Kingdom. Canadian nonscheduled carriers, renowned for the part they played in building up Canadian aviation, particularly in the northern sections, continued their activities under government regulation.

An operation in the U.S. planned by several small companies after the war, was an air ambulance service. New to the U.S., this type of operation had long been used in several other countries, notably Australia. The Australian flying doctor service, financed by private contributions and government funds, furnished ambulance service and medical aid to isolated "out-back" settlers. In 1946 it covered half the area of Australia from a chain of seven main bases, each equipped with radio communication facilities.

Another world-wide service was aerial photography. Before the war, aerial photography had proved its value in such activities as mapping and soil conservation work. In 1937, a program of photographing some 68,420 sq.mi. of the United States "dust bowl" was completed. Aerial photography played a vital war role, with the armed services using it extensively as a strategic and tactical aid. A military program which was of value to civilian aviation was the aerial mapping of 19,000,000 sq.mi. of world airways by the U.S.A.A.F. Notable wartime developments in aerial photography included the automatic electric flash unit for night photography, colour photography for greater detail, photography from as high as 40,000 ft. and the radar camera.

Well established in Canada, where mining companies had used their own planes for many years, company ownership and operation of aircraft for the movement of personnel and supplies was becoming widespread in the U.S., especially by concerns having factories scattered throughout the country. Aerial services also continued to be useful in farming, especially crop dusting, forest and wildlife conservation, city planning, air advertising, etc.

Private Flying and Training.—Although private flying and training ordinarily had constituted two distinct, though related aspects of civil aviation, the two became largely identical during a major part of the ten-year period; in wartime the activity of the private pilot was interwoven with military training.

For many years prior to World War II, the governments of most European countries showed great interest in private flying, promoting it through subsidies. The British commonwealth countries had subsidy programs for their aero clubs carried out primarily through the grant of a bonus for each pilot certificated. In the U.S., although there were many private training schools and probably more private flying than in any other country, no government aid was given until 1939, when the civilian pilot training program was established in schools and colleges.

With the outbreak of war, private flying in most belligerent countries was grounded, and planes were taken over by the military. But the activities of the civilian pilot, though changed, continued. England, in Sept. 1939, organized the air transport auxiliary which utilized civilian pilots to ferry aircraft from factories to R.A.F. stations, principally in the British Isles. Having some 1,500 pilots, the A.T.A. delivered approximately 340,000 aircraft. In Canada, civilians of the aero clubs and commercial aviation concentrated on the operation of elementary flying and air observer schools for the British commonwealth air training plan set up in Dec. 1939 and based in Canada to train men from all parts of the commonwealth and empire.

Entry of the U.S. into World War II substantially reduced pleasure flying in that country also. Civilian pilots found their places as instructors in civilian schools, training personnel for the armed forces. They also staffed the Civil Air Patrol, an organization performing such necessary military functions as coastal and border patrol, courier service, tow target and tracking work and rescue and relief work.

With the end of the war, private flying began to resume peacetime activities. Australia continued the prewar plan of assistance to the aero clubs. Private flying was again under way in Canada, led by the aero clubs, under their title of "Royal," awarded by the government in recognition of war services. Although lack of aircraft and airports and the high cost of the available planes impeded widespread resumption of flying, some relief was obtained following the release of surplus equipment and military fields by the government. In the United Kingdom a similar situation prevailed. Civilian activity at the end of 1946 was hampered by the lack of equipment, gasoline shortages, high costs and the abandonment of the govern-

ment aero club subsidy plan. Here also the release of surplus equipment and aerodromes to the clubs helped some. Nevertheless many people felt that sailplanes offered the only immediate solution for private flying.

In 1944, the U.S. government stopped its direct civilian

training program, which in the four years of its existence had instructed 397,812 persons. However, the government was indirectly stimulating private flying both by a veterans' education program and by a tremendous airport construction program.

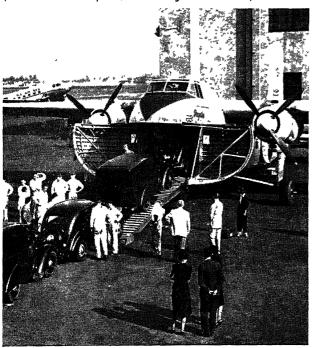

Probably the strongest impetus to private flying came from the return to civilian life of military personnel, many of them trained pilots and most others air-minded. It was clear that private flying, despite some hindrances, was on the threshold of its greatest expansion. Proof of this was the fact that U.S. private plane manufacturers had 40,000 orders at the end of 1945, and despite record production in 1946, still found a substantial demand for new planes at the end of the year.

Government.—Dwarfing all other government activities in the international field was the International Civil Aviation conference held in Chicago in 1944. The 54 nations at the conference drafted four far-reaching agreements: (1) a convention to set up a permanent international civil aviation organization; (2) an interim agreement to set up a temporary body known as the Provisional International Civil Aviation organization (P.I.C.A.O.); (3) a "transit agreement"; (4) a "transport agreement." The last two set up the "five freedoms" of the air enabling the aircraft of a country to fly over and land in other countries for nontraffic purposes, to take on or discharge in such countries passengers originating in or destined to the homeland of the aircraft, and to take on in one foreign country passengers destined for another foreign country. By the fall of 1946, 12 nations had deposited ratifications of the

The Bristol twin-engine cargo plane shown during a loading demonstration at La Guardia field, N.Y., on Sept. 19, 1946. Britain's first postwar commercial plane, it was designed to land a 6,000 ton load

permanent convention, 46 the interim agreement, 29 the transit agreement and 15 the transport agreement.

Limited acceptance of the transport agreement left traffic rights between most countries to be settled through bilateral agreements. In 1946, numerous such agreements were concluded, including that reached at the Bermuda conference between Great Britain and the U.S.

In 1945, P.I.C.A.O. was established in Montreal; the first meeting of the assembly was held in 1946. Regional conferences called by P.I.C.A.O. were held in 1946 to develop an efficient system of navigational aids for international use. By the end of the year, important recommendations of these conferences were under consideration.

Also growing out of the Chicago conference, though not a governmental organization, was the International Air Transport association, successor to the prewar European International Air Traffic association. Its purpose was to provide machinery for co-operation between international air carriers. By the end of 1946, agreement on international rates and standardization of traffic procedures had been facilitated through I.A.T.A.

In individual countries, national governments assumed a major role in civil aviation. The U.S. government avoided ownership or management of air services, relying on regulation of private enterprise. With only safety supervised in 1937, the Civil Aeronautics act of 1938 provided comprehensive safety and economic regulation. Administration of the act, originally vested in a Civil Aeronautics authority, was subsequently divided between two agencies, the Civil Aeronautics board and the Civil Aeronautics administration. Among other things, the CAB was given responsibility for controlling economic matters, including authorization of new routes and the fixing of rates, promulgating safety regulations and accident investigation; the CAA, for enforcing the safety provisions, licensing airmen and aircraft, developing and maintaining airways.

In the administration of the act, major government policies emerged. The authorizing of American Export Airlines to operate Atlantic services in addition to those of Pan American evidenced the intent to have competition among U.S. international services. Requiring American Export's steamship parent to divest itself of control of that air line in effect barred surface carrier participation in international and interstate services. The certification of several small new companies pointed to a network of trunk lines operated by the large carriers, and local or feeder lines by smaller regional carriers. A major problem remaining in 1946 was that of the nature and extent of the economic regulation that should be exercised over nonscheduled carriers.

In the Civil Aeronautics act, the government committed itself to subsidizing air service by basing payments for the carriage of mail on the financial needs of the carriers, and the major attention of the CAB was devoted to determining such mail rates. Although all certificated carriers originally received payments amounting to substantial subsidies, improved financial results of operation enabled the CAB in 1942 for the first time to reduce the compensation of a carrier below the subsidy level. By 1946 the larger domestic carriers operated without subsidies; however, the international operators and smaller domestic lines still received financial aid. Although possessing powers to fix passenger rates for domestic services, the steady reduction in passenger fares by the carriers obviated the necessity of exercising those powers during the period.

Another important government move came not from

250 the CAB, but the post office. With air mail having always required a substantial surcharge, the post office in 1946 announced the establishment of a five-cent postage rate for air mail inside the U.S. and to its possessions, reducing the surcharge to only two cents.

Despite assumption by the U.S. government of exclusive control over broad phases of aviation, both state and local governments continued extensive activities. These were devoted primarily to licensing and otherwise regulating intrastate services, airport development and co-operation with the federal agencies.

The governments of the British commonwealth nations were equally active. In 1943 and 1944 intergovernment conferences resulted in the establishment of pooling and other co-operative arrangements in the services between the countries and the setting up of the Commonwealth Air Transport council, an advisory body.

In the United Kingdom, the regulation of economic and safety aspects of civil aviation was a function of the air ministry until 1945, when a ministry of civil aviation was established. In prewar years, government participation in air transport was effected through subsidies to private companies. The first direct government participation, except for wartime emergency measures, came with the establishment in April 1940, of British Overseas Airways corporation to operate all external services. This organization was controlled by the government through majority stock ownership. Complete government ownership of scheduled air transport followed in Aug. 1946, with the passage of an act nationalizing existing transport companies and providing for operation of all services by government-owned companies. The plan called for three organizations: British European Airways to operate internal and continental services; British South American Airways to fly Latin American routes; and British Overseas Airways corporation to conduct remaining services.

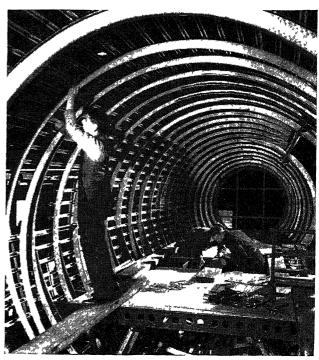

A leader in air mail development, the British government in 1938 completed the famous empire air mail scheme to carry without surcharge all first-class mail between many parts of the empire. Suspended in 1939 because of lack of equipment, the service had not been resumed at the end of 1946.

Australia followed a course somewhat similar to that of Great Britain. The administration of the Air Navigation act and regulations was transferred from the department of defense to the department of civil aviation in 1939. In 1945 a law to nationalize the internal scheduled air carriers was passed. Although the nationalization provisions of the bill were declared void by the high court, the government withdrew its subsidies to private companies and established its own company, Trans-Australian Airways, to operate in competition with them. The government also participated through direct ownership in Australian international companies.

In Canada, with the government already regulating certain phases of civil aviation in 1937, a series of changes in both the nature and extent of government regulations and the modes of administering them resulted in a comprehensive system by 1946. In April 1937, the government began direct participation in air transport with an act to establish and control, through its Canadian National Railways, Trans-Canada Airlines for the transcontinental services. The scope of government activity increased when, in 1944, the government announced the designation of Trans-Canada as the sole operator of internal trunk lines and international routes. Government control of the largest air line did not, however, exclude private companies from the field.

Production.—In 1937 the U.S. was producing mostly civil aircraft, but the European countries, spurred on by Germany, were beginning large-scale production of military planes as rapidly as expanding facilities would permit. At the outbreak of the war in Europe, Germany led in the number of planes produced, with England, despite progress, far behind. Notwithstanding the stimulus to both increased production and a shift to military planes that had come with large orders from Great Britain and France, the U.S. still concentrated on civilian planes and trailed England in volume of production.

By 1944, when peak production was reached, the picture was altered greatly. Production of planes for civilian use had ceased, while the volume of military production had reached staggering proportions. The five large warring nations were together producing approximately 250,-

Fuselage of the British airliner "Hermes," a four-engined passenger plane. It was designed to have a seating capacity of 34-50 persons and a cruising speed of about 240 m.p.h.

000 military planes annually; the U.S. production was nearly double that of its nearest rival. From 1940 to 1944 the numbers of military planes produced in the U.S. increased approximately 1,500% and the airframe weight approximately 4,500%, the greater proportional increase in weight reflecting the shift from fighters for defense and light planes for training to heavy bombers for attack. During 1944, U.S. military aircraft products alone had a value of \$16,745,000,000, while in 1940 both civil and military aircraft products had a value of \$859,866,383. The enormous expansion of the U.S. aircraft industry was illustrated by the fact that the 97,600 employees in Jan. 1940 had grown to 2,079,900 in Jan. 1944.

After V-J day, tremendous cutbacks were made, and production dropped sharply. In the United States, military contracts for \$9,000,000,000 worth of aeronautical equipment, including 31,000 planes, were cancelled on a single day. With its great plant capacity, and already producing large numbers of heavy bombers and transports for military use, the U.S. swung into production of commercial transports with relative ease. England, having concentrated on fighter and pursuit planes during the war, and with military orders lasting longer, was slower in converting. Nevertheless, in both countries, production of civilian planes was assuming its peacetime role by the end of 1946. England was relying on her lead in the jet engine industry to offset this initial disadvantage in the production of commercial transports.

The methods developed to accomplish the wartime feats were of great importance to postwar civilian production. Undoubtedly mass production was achieved, although, contrary to some early predictions, automotive techniques were not wholly applicable. Standardization, more extensive tooling and a breakdown of operations were outstanding. Two problems left unsolved were the rising cost of production and the length of time required to introduce new models into production.

The foundation of much of the increased production during the war was the construction of government-financed factories. Plans in different countries varied. In some cases the plants were owned by the government and operated by the government or by private industry; in others they were owned by private companies subsidized by the government. After the war, some governments continued participation in aircraft production. The U.S. government, however, which had followed the plan of government ownership and private operation during the war, was selling its plants.

An aftermath of wartime production in the United States was the large number of aircraft declared surplus by the armed forces and placed on sale to civilians. By Sept. 30, 1946, the War Assets administration, the government disposal agency, had net acquisitions of salable aircraft of all types with a reported cost of \$1,421,369,000. Disposal as of the same date amounted to \$770,354,000 reported cost. U.S. surplus aircraft together with lend-lease aircraft comprised a major part of the air line equipment of the world in 1945 and 1946.

Wartime strides in production were not limited to the large industrial nations. Canadian and Australian production, although not comparable in volume with that of the U.S. and Great Britain, showed equally amazing progress. In Australia an embryonic industry, with no general organization and few skilled aircraft technicians, importing most of its raw material and complex components such as engines, and capable at best of turning out only a few light planes, developed into a largely self-sufficient unit able to produce modern transports and front-line fighters and bombers. This growing industry produced 3,526 military planes from Sept. 1939 through Aug. 1946.

The prewar Canadian industry, though already producing one highly successful type of purely Canadian design, the twin-engine Noorduyn Norseman, was a minor industry. With about 3,000 employees in 1939, it grew by 1944

to an industry of more than 120,000 workers, producing a substantial number of military planes, including Lancaster and Mosquito bombers. In 1946, Canada was producing, under licence, DC-4s with Rolls-Royce Merlin engines for use on Trans-Canada Airlines and was expanding jet development and gas-turbine jet-engine work begun during the war in greatest secrecy. Plans were under way for the manufacture of helicopters, and a new Canadian light plane design, the Noury Noranda, had been announced.

Aids to Navigation.—Before 1937, adequate navigation aids were recognized as essential to safe and efficient operation, since only with them could aircraft fly accurately to their destinations and operate safely at night and in bad weather. Throughout the world, experimental work resulted in a multitude of complex systems, confusing to the layman. The prewar U.S. system was probably the most extensive. Its basis was a network of governmentowned and operated airways, with radio range stations, radio marker beacons, weather reporting stations, traffic control stations, teletype service, lighter beacons and intermediate landing fields. The backbone of the airways was the radio range, emitting beams to guide the pilot along his course. Other western hemisphere countries followed the U.S. plan.

Prewar Europe had no government-designated airways. Systems there were based on the use of radio direction-finding with ground direction-finding most widely used. Ground stations determined the position of the aircraft from radio waves transmitted by airborne equipment and advised the pilot of his position.

It was agreed that the 1937 systems were inadequate because of the limited number of facilities and the technical shortcomings of those facilities. Work in the tenyear period attacked the problem from both angles. A major improvement was the development of very high frequency radio equipment, which was comparatively static free. In 1937, Australia, taking advantage of German experimental work, began the installation of 11 very high frequency radio beacons, and the U.S. in 1941 completed an experimental very high frequency radio range between New York and Chicago. The war interrupted plans for converting all medium frequency ranges in the U.S. With the return of peace, a program to accomplish this was under way.

Another improvement was the omnidirectional range. Unlike existing ranges which supplied four set courses, the omnidirectional range, by means of a rotating radio beam, supplied courses in all directions from the station. In 1946, the United States planned to gradually install omnidirectional ranges on all airways.

Although manually-operated airborne radio direction finders had been in use for some years, it was not until the late 1930s that an effective automatic finder was introduced in the United States. This was followed by the dual automatic direction finder. So efficient were these that in 1941 the CAB, faced with increasing airways congestion,

announced that transports equipped with such devices could fly off the radio ranges.

Much attention centred on instrument landing systems With three types in use at major airports in prewar Europe, efforts were directed to developing still better systems. In 1938, the United States CAA was able to announce an improved scheme, and during the war the armed forces continued this work. One of the war-tested systems was SCS-51, incorporating the CAA principle, and visually portraying on a single instrument in the plane all necessary information for a blind landing. Adopted by Great Britain and the U.S., SCS-51 equipment was being installed at 50 airports and on many transports in the U.S. in the summer of 1946.

Holding greatest promise for air navigation was radar (q.v.). Applied to flight navigation, instrument landing, distance finding and collision prevention, radar offered

Air distances from the capitals of four nations to other important cities shown on azimuthal equidistant projection maps. This type of map, ideal for computing air distances, is centred on a chosen spot (in each of the above four, the capital). A straight line on the map connecting the centre spot with any other spot on the map is the shortest distance between the two points, a great circle route

almost unlimited possibilities. Although radar research dated back to the 1920s and radar detection stations for military use had been erected in England by 1935, the war produced the major radar developments. While most wartime radar devices required further work for commercial application, some were already in use in 1946. One was ground-controlled approach (GCA). Used successfully by the armed forces during the war as an instrument landing system, the immediate civil use of GCA appeared to be as an airport traffic monitoring device, permitting personnel on the ground to locate accurately, through the radar scope, planes in the vicinity of the airport. In 1946,

GCA had been obtained for three U.S. airports. Two radar flight navigation systems used during the war, the short-range British Gee and the long-range U.S. Loran, were also considered capable of immediate application in civil flying.

Each year the increasing number of planes on the airways and at airports made traffic control a more acute problem. To meet this problem the United States completed an airway traffic control program and set up traffic control centres.

Radar devices were looked to as the probable solution to the airport traffic control problem.

The various aids to navigation installed throughout the world for the armed forces in the war were a great boon to civilian flying. The northwest staging route in Canada, completed as a wartime airway providing an inland route to Alaska and Asia, was a notable example.

Technical Developments.—In prewar Europe, governments played a relatively larger part in research and development in their countries than did the government in the United States. In all countries during the war both government and private research was stimulated to unprecedented activity. In the United States the principal government research agency, the NACA, with adequate funds for the first time, assumed an increasingly important role. The postwar pattern for the U.S. and England appeared to be government research, including military research, working closely with the research of the private aircraft industry.

The trend toward larger, faster planes, under way in 1937, continued at an accelerated pace. Already in operation on the air lines by 1946 were 69-passenger, 300 m.p.h. planes, with transports of 400 m.p.h. soon to be in use. Development in transport aircraft during the decade turned to multi-engine landplanes. With increased range and ability to maintain flight with one or more engines inoperative, they were used by 1946 not only for land but also for transoceanic operations, largely replacing the prewar flying boat. After the war, planes designed expressly for hauling cargo were receiving wide attention.

In the light plane field, with production nonexistent during the war except for a few models to meet military needs, the plane of 1937 still dominated the field in 1946. The De Havilland Tiger Moth in the British commonwealth and the Piper Cub in the U.S. were still the major training planes. New designs, however, were appearing, with emphasis on utility for the individual owner. One of the most popular was the spin-proof plane. Offered in 1946 were larger planes with higher horsepower, all metal construction, retractible tricycle landing gears, flaps, improved propellers, better instruments and radio as standard equipment.

Not all emphasis was on conventional aircraft with increased size and speed. Although the idea of incorporating all functions of the fuselage and empennage in the wing had been experimented with for years, practical results were achieved under the impetus of war. In 1946, the XB-35 prototype (Northrup Flying Wing) completed a successful first flight, and Armstrong-Whitworth in England was nearing completion of a jet-propelled tailless transport.

By 1937, the desirability of multi-engine transport aircraft from a standpoint of safety was established, but opinion differed on the most desirable number of engines for planes of different types and purposes. Before the war the German JU-52, a trimotor, was widely used throughout the world for passengers and freight, and the U.S.S.R. had two-, three-, five- and six-engine planes. Although the

U.S. and Great Britain emphasized two- and four-engine equipment, a number of planes with three, six and eight engines were in production in 1946.

All countries showed renewed interest in the pusher-type plane. By 1946 such planes, large and small, were being developed and in some cases actually produced. An interesting one was the Douglas XB-42 with propellers in the tail and power plants in the fuselage. This also exemplified the plan of submerging the engines in the fuselage or wing which resulted principally from research to reduce drag. Other notable research to increase performance through reduced drag in the conventional cantilever wing monoplane, the basic design of the period, was done by the NACA. Its accomplishments, particularly in new wing shapes, constituted high points of the decade 1937–46. Also appearing were wings with greater sweep-back, thought to be a partial answer to the problem of compressibility in transonic flight.

A necessary part of the general progress was the development of improved power plants. In 1937, the most powerful engines produced approximately 1,200 horsepower. The need for larger and faster warplanes called for more powerful engines. In the midst of the struggle to meet this need, the controversy over the relative merits of liquidand air-cooled engines reached new heights. Whatever their relative merits, both became widely used, and their horsepower increased steadily. By 1946, a 36-cylinder, 5,000-horsepower, air-cooled engine was announced by a U.S. manufacturer. And these increases were achieved with only slight proportional increases in the weight of the individual units.

Contributing to better performance was the steady improvement in superchargers, especially in the U.S. turbosupercharger. Superchargers developed during the decade increased take-off efficiency and made possible high altitude flight. Another corollary to high-altitude flying was the pressurized cabin, introduced on a commercial plane in 1940 in the U.S.

Experimented with in all countries, the diesel engine found application in Germany's Junkers Jumo 205. The Germans, feeling that the diesel was effective where exceptionally long range and economy of operation were desired, used this engine extensively.

A particularly important development with unlimited potentialities was the introduction of practical jet propulsion. The major advantages of jet engines were held to

be their great power, accompanied by light weight and adaptability to aerodynamic cleanness. Behind jet progress was metallurgical research, producing metals capable of withstanding extreme heat and power stress. A successful jet flight was conducted in Italy in 1940. In May 1941, the first successful jet-propelled aircraft was flown in England. This plane had a gas-turbine jet engine based on a design of Air Commodore Frank Whittle. Produced under wartime secrecy, a model of the Whittle engine was sent to the United States and on Oct. 1, 1942, the first U.S. jet-propelled aircraft was flown. Out of this development came such aircraft as the Gloster Meteor and the Lockheed Shooting Star, fighter planes with speeds exceeding 600 m.p.h.

Germany developed jet propulsion to an amazing degree, particularly rocket propulsion as applied to guided missiles. While U.S. and British research concentrated on the gas-turbine jet engine, the Germans, for military purposes, also developed the intermittent-duct jet engine used in the buzz bomb, V-1; the athodyd, or ramjet, flight-tested in the fall of 1944; and the rocket motor, used in the famous V-2. The advanced position of German rocket research was shown by the fact that at the end of the war Germany was building a pilot-controlled, liquid-fuel rocket powered bomber, planned to fly from Germany to New York in 40 minutes. German research stimulated efforts the world over to achieve piloted flight at supersonic speeds.

The application of the jet principle to commercial planes began to be a reality in 1946. Several types of transports under construction, having conventional reciprocating engines and propellers, utilized the engine exhaust to supply jet thrust for additional power. Although still experimental, the British flew an Avro Lancastrian equipped with two conventional engines and two jet engines, using the conventional power plants for take-off and the jets in flight. Speed with the two jets alone was reported to be 100 m.p.h. greater than with four conventional engines.

Propeller improvements kept pace with engine developments. Propellers so constructed that the pitch of the blades could be changed in flight were in limited use in 1937. By 1946, the controllable-pitch propeller, adjusted by the pilot, and the constant-speed propeller, adjusted automatically, were in general use on large planes. Also brought into general use during the ten years was a feather-

The "Ensign," a low-winged two-seated monoplane designed for private business or recreation flying. Featuring a plexiglass canopy and a practical cruising speed of 112 m.p.h., it was first exhibited in the U.S. in Sept. 1940

ing device which made possible adjustment of the blades to prevent auto-rotation in the event of engine failure. A further extension of the principle of adjustable blades was made in 1944 with the introduction of the reversible pitch propeller, used as a landing brake. Increased size and strength were achieved without proportional increases in weight through the use of hollow steel propellers. Three-and four-blade and contra-rotating propellers, the last consisting of two propellers revolving on the same axis, but turning in opposite directions, were installed on a growing number of planes.

The tricycle landing gear, just coming into use in 1937, was adopted for all larger planes and many postwar light planes. Fast disappearing was the fixed landing gear, replaced by the retractible gear, mechanically drawn into the wing or fuselage during flight.

Metal, particularly aluminum alloys, continued to be the dominant material in aeroplane construction. Fabric, formerly widely used, was relegated to the light plane field. War demands and shortages intensified research into all possible materials and resulted in a return to wood, the introduction of moulded plywood, increased use of plastic, and a variety of metals including stainless steel and magnesium. While flush riveting to eliminate drag caused by exposed rivet heads was being adopted at the beginning of the decade, with the Germans and British leading, this method did not become a standard practice until after the outbreak of war. In addition, various techniques of welding were introduced and widely accepted in aircraft construction.

Recognized as essential to safety and efficiency of operation, devices for the prevention of ice formation on wings, propellers and control surfaces were appearing on transport aircraft in 1937. The most widely used de-icers consisted of pulsating rubber boots at the critical spots. During the war, the U.S. army air forces employed the new, NACA tested "hot wing" de-icing. In 1946, most U.S. transports in production incorporated this principle of thermal de-icing, and its installation on existing transports was planned.

Remarkable changes took place in gliders. Used principally for sporting purposes before the war, the glider became an important military weapon with the advent of aerial warfare. The light, soaring planes became flying boxcars towed by a powered aircraft. The U.S. CG 13A, about the size of a DC-3 and capable of carrying 4,000 lb., was typical of the advanced designs. It was predicted during the war that such gliders would be used commercially for postwar cargo carriage; however, by 1946 this application had received only minor acceptance. (See GLIDING.)

Rotary Wing Aircraft.—Catching the public fancy to as great a degree as any event in the history of aviation was the development of rotating wing aircraft, represented chiefly by the Autogiro and the helicopter. The Autogiro, having a conventional power-driven propeller in the nose and a large rotor above the fuselage, demonstrated its practical application when, in 1939, Eastern Air Lines conducted Autogiro mail service from the roof of the Philadelphia, Pa., post office to the airport.

Major emphasis of the decade, however, was on the helicopter. Lacking fixed wings and conventional propeller, the helicopter with a power-driven rotating wing could go forward, ascend and descend vertically, move to either side or backward, and hover without moving. Its acceptance, speeded with the successful flights in Germany in 1937 of the Focke-Wolfe 61, came still closer when the first U.S. helicopter, a Sikorski, was flown in 1939. Shortly afterward, the U.S. armed forces ordered similar

The helicopter was expected to revolutionize postwar civil aviation and provide a means of mass private transport. Here a helicopter pilot demonstrates how supplies can be dropped to persons marooned in inaccessible areas, or how rescues can be made by rope ladder

craft from several helicopter manufacturers. Used for patrol, search and rescue work by the military services, the practical value of this type of aircraft was established during the war.

CAA certification of a Bell design paved the way for civilian use in the U.S. In 1946, the U.S. post office department conducted successful experimental mail services using helicopters in the metropolitan Los Angeles and Chicago areas. Numerous requests before the CAB for authority to operate helicopter routes indicated a widespread interest in the commercial possibilities.

By the end of 1946, civilian production was under way. Among the many types being experimented with were the familiar design with one main overhead rotor and a small tail rotor; and newer designs with two main rotors arranged coaxially, intermeshed, outboard, or tandem, having power supplied by one or two engines. In England a helicopter was developed utilizing jet to counteract the torque of the spinning rotor. (See also Airports and Flying Fields; Aviation, Millitary; Disasters; Petroleum; Post Office.)

Aviation, Military

An outstanding feature of the momentous decade (1937–46) that contained history's most devastating and only truly world-wide war was the clear-cut demonstration of the new and decisive part played by air power in relation to the other armed services. In the main there were two theories as to the proper use of air power. Some, following the classic pattern of Karl von Clausewitz, said its role should be merely one of co-operation with land and surface forces. Others, following the Italian General Guilio Douhet, the U.S. General "Billy" Mitchell and Great Britain's Lord Trenchard, claimed that air power alone was sufficient to achieve victory and should be used independently of other forces. As we-shall see as we trace

(G. M. M.)

world military aviation through, the decade 1937–46, there were elements of truth in each theory. For complete victory air power was used as a strategic weapon by striking the enemy directly through the air without the aid of surface arms: as a tactical weapon in close co-operation with ground and sea forces; and somewhat unexpectedly as a logistic weapon, a modern method of rapidly transporting men and munitions to the fighting fronts, salvaging many a critical situation.

It will be convenient to divide the decade into four parts. (1) Jan. 1937 to Aug. 1939, the prewar period, Europe; early stages, the air war in China. (2) Sept. 1939 to Dec. 1941, the air war in Europe and the Mediterranean, early stages. (3) Jan. 1942 to May 1945, the rest of the air war in Europe, and Dec. 1941 to Aug. 1945, the air war in the Pacific and Asia. (4) Aug. 1945 to the end of 1946, postwar trends of military aviation.

World's Air Forces, 1937-38.—Germany.—By Jan. 1937 the German air force, or luftwaffe, had been officially in existence for two years, although actually in existence at least four. From the mid-1920s the Deutsche Lufthansa had operated a network of air lines which gave Germany the paramount position in civil aviation in Europe. In 1931 Hermann Goering formed the National German Air association, by means of which the nazi party obtained virtual control of German aviation. When Adolf Hitler came into power in 1933, Goering became minister for air and at once began to secretly build up the luftwaffe. He put on an enormous promotion program among the Hitler youth and raised the number of flying and glider clubs in the Deutscher Luftsportverband from 300 to 2,500 and total membership to 500,000; he reorganized them with a strong military slant and called them Landesgruppen (regional groups). In March 1935 the creation of the luftwaffe was officially announced, with Goering as commander in chief. In view of his activities of the preceding five years he was able to muster 1,000 first-line military aircraft and 20,000 officers and men. He put on impressive demonstrations for the air attachés of various countries represented in Berlin.

The military aircraft consisted at that time almost wholly of Heinkel, Junkers and Dornier twin-engine bombers, adapted from commercial transports, with speeds averaging 220 m p.h. There were also good numbers of Junkers Ju-52 tri-motored transports, and a few Ju-90 and Focke-Wulf 200B Condor four-engine transports. There were two dive bombers and ground attack planes, the Henschel 123 biplane (B.M.W. 850-h.p. air-cooled radial engine, top speed 248 m.p.h.), and the more lately developed and quite remarkable Junkers Ju-87 "stuka" (sturmkampflugzeug), powered with a Jumo 800-h.p. 12cylinder inverted V-engine; diving speed was slowed to 248 m.p.h. by "venetian blind" brakes. Two secretly developed biplane fighters were the Arado 68 (B.M.W. 132 air-cooled nine-cylinder radial of 750 h.p.; top speed, 210 m.p.h.), and Heinkel 51 (B.M.W. 116 liquid-cooled, 12cylinder inverted V-engine, 750 h.p.; top speed, 225 m.p.h.). Both were used as fighter-trainers as soon as the low-wing Messerschmitt 109 was available in quantity.

All of these types of military aircraft were sent to Franco's forces in Spain beginning in the summer of 1936—a total of some 200 combat planes and 50 Ju-52s in support. The Spanish Civil War was an experimental laboratory for the luftwaffe in which military aircraft characteristics, air tactics and air-ground co-operation were tested and invaluable combat experience was gained.

Many defects were revealed and corrected, and as much as any single factor this experience accounted for the initial success of the luftwaffe in World War II.

At the beginning of 1937 the German air force had about 2,500 first-line combat planes. These included 400 medium bombers, with 700 in reserve, consisting of the Heinkel 111K, Junkers Ju-86K and Ju-88, Dornier 23 and 17S, the latter nicknamed the "flying pencil." (The letter "K" was used in the designation of bombers converted from corresponding commercial transports, and stood for krieg, or "blow"). Light bombers, including the Henschel 123 and Ju-87, numbered about 300 with 400 in reserve. There were also about 300 fighters, with 400 in reserve, including the He-51 and early versions of the Me-109, one of the outstanding fighters of the entire war. The big drive to make the luftwaffe the world's biggest and best air force was not yet reflected in first-line strength, though it was big enough to serve as political propaganda.

At this stage the luftwaffe organization was efficient and riding high politically. The German air staff in Berlin had Goering at the top, with hard-working Erhard Mılch as his deputy. Jeschonnek was chief of staff, and the likeable, clever Ernst Udet chief of aircraft design and supply. These men who built the luftwaffe were greatly influenced by Douhet, the R.A.F. leaders and Mitchell. Hitler and Goering wanted an independent air force that would win the war speedily and without disrupting the economic life of the conquered countries. The German army general staff, however, was determined that the luftwaffe should be used as an auxiliary force only, a spearhead for lightning blows (blitzkrieg) by the ground forces, particularly the panzer units, a view which finally prevailed. In any case the top echelon of the German air force missed the strategic air power boat by failing to appreciate the main air power weapon—the heavy bomber. Goering, Milch and even Udet were all against heavy bombers as too slow and vulnerable, although Udet as director of research and development was mainly responsible for the choice of German aircraft types. They wanted the luftwaffe to be fast, to rely on their fighters and on the speed of their light and medium bombers. This failure to grasp the import of the air power weapon lost them the battle of Britain, and the war.

The German air force, however, in the 1937–38 period, largely because of its dress rehearsal in the air war in Spain (ended March 1939), was much better trained, organized and equipped to fight a modern war than were contemporary European air forces, and this fact was a trump card in the scheming hands of Hitler, Goering and Joachim von Ribbentrop. First-line strength expanded from 1,000 aircraft in 1935 to some 4,000 in the summer of 1939. They wanted another year to ensure a quick, overwhelming victory, but events turned out otherwise.

U.S.S.R.—The strength and quality of the air forces of the soviet union during the mid-1930s was one of the big question marks in world military aviation. Opinion abroad tended to accept the view that the Red air force was not of much account. This view was strengthened when Charles Lindbergh in 1935, after a somewhat exhaustive tour of the German aircraft industry, followed by a visit*to Russia, greatly deprecated what he had seen of military aviation in the soviet union. Exceptions to this view were found in the reports of the French air attaché at Moscow, in the statement of Col. Hilmer von Buelow in a German military intelligence publication, and a bit later in the account of the British military analyst,

Capt. B. H. Liddell Hart in his book Europe in Arms (1937). The facts tended to confirm this minority opinion. Russian military aircraft and pilots did surprisingly well in the Spanish Civil War. Best known of all were the I-15B biplane fighter called the Chato, meaning "flat-nosed" in Spanish, and the I-16 bee-shaped low-winged monoplane known as the Rata, or Mosca (Spanish for "fly"). Best-known Russian bomber which saw service in Spain was the ZKB-26, called Katuska. These three aeroplanes were as effective as any others in the world, at that time, more so than the early German types sent to Spain.

At the beginning of 1937 it was thus more than probable that the Russian air force was the greatest on the continent, although not generally recognized as such at the time. First-line strength was estimated at 3,400-3,500 machines. It was at this time that the flying society known as the Aviakhim (formed in 1925) was merged with the O.S O. (Society for Assistance to Defense) and greatly expanded as the famous Osoaviakhim. Russian youth was enthusiastically air-minded; the elements of aeronautics were taught in the schools; gliding and parachute jumping were universal sports. In Dec. 1936 a 150,000 pilot-training program was started, completed 15 to 18 months later. Prior to this program there were between 15,000 and 20,000 pilots. The ground crew and service facilities in Spain were superior to those of the Germans. There were 11 aircraft plants, some of which produced new planes, others repaired and serviced existing planes, including trainers. At this time there were three principal engines being produced, all under licence from foreign governments. These included the M-25 (based on Wright Cyclone), the M-88 (from the French Gnome-Rhone) and the M-105 (French Hispano-Suiza). The Central Aero Hydrodynamics institute at Moscow was the seat of Russian research and development in military aviation.

The soviet air leaders showed a clear grasp of air strategy and tactics, especially as applied to combined operations with other forces, but laid less emphasis on strategic air warfare against key industrial targets of an enemy nation as developed by the R.A.F. bomber command and U.S. army air corps. The Russians were first to make tactically significant such developments as the parachute army, troop-carrying gliders and airborne infantry, as well as "storm" aviation—the use of heavily armed and armoured low-flying attack planes against enemy troops and ground objectives.

Organizationally, there were two army air forces, one in western Russia, with some 1,800 first-line planes in 1937, and one in eastern Siberia, with possibly 1,300 planes. The naval air forces consisted of shore-based aircraft, seaplanes and flying boats, totalling a probable 300 of all types. The soviet air forces of the west were, as a whole, commanded by a chief of the air force, who acted as air adviser to the chief of the general staff of the Red army. There was also an independent striking force, but this was not very active before 1942.

France.—The French Armée de l'Air, largest air force in the world during the early 1930s, had very definitely dropped behind the parade by Jan. 1937. Numbers were still there, but of the 3,600 combat aircraft on hand (1,200 to 1,500 first-line machines), more than 50% of the planes and engines were obsolescent or obsolete. Having failed to establish a sharp line of demarkation between first-line aircraft, obsolescent and obsolete equipment, the results of the not inconsiderable French aeronautical research and experimental efforts, mainly at Chalais-Meudon, could

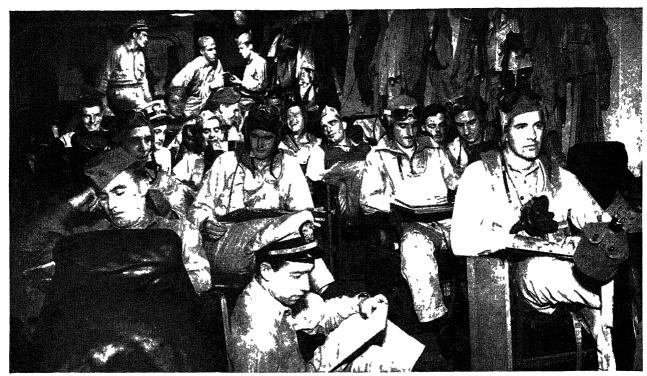

not be translated into production of new equipment until the older stuff was written off the books. The famous aircraft firms of Dewoitine, Potez, Morane-Saulnier, Bloch, Nieuport and Amiot had a promising batch of experimental monoplane fighters and a new series of high-speed bombers in prototype stage, but most of them never got into production. The French air establishment contained about 4,000 pilots and 50,000 ground personnel. The 1937 training program called for an additional 1,000 pilots and 9,000 personnel.

Things went from bad to worse in 1938. The technicians were losing their interest under the nationalization scheme started in 1936. Products of the French plants were neither as numerous nor as efficient as those coming off the assembly lines in other countries. The training program also lagged. More than half of the machines in the French air forces were not fit for active service against a first-class power. This applied particularly to the French engines of that period. Technical observers from the United States making aeronautical surveys of Europe (including Great Britain) in 1938 ranked France last in both numbers and quality of aircraft. The best fighter was the Morane-Saulnier 406, powered by a 12-cyl. Hispano-Suiza liquid-cooled engine of 860 h.p. and having a top speed of 300-310 m.p.h. A fair performer was the Potez 63 fighter, attack bomber and reconnaissance plane, powered by two Hispano-Suiza 14-cyl. air-cooled radial engines of 670 h.p.; top speed, 285 m.p.h. A 310-m.p.h. medium bomber was the Amiot 350, powered by two Hispano 12s, and the Bloch 131 with two Gnome-Rhone 14cyl. radials of 880 h.p., top speed 250 m.p.h. Armament of these planes consisted of Hispano-Suiza 20-mm. and 23mm. cannon. To augment this force in the winter of 1938-39 orders were given the U.S. aircraft industry for Pratt & Whitney and Wright radial air-cooled engines, Curtiss 75-A Hawk fighters, Martin 167 medium bombers and Douglas DB-7 light bombers.

Italy.—The remarkable rise and sharp decline of the Italian air force was one of the notable phenomena of the decade 1937-46. At the beginning of 1937 the Regia Aeronautica or Royal Italian air force was rightly reckoned among the world's greatest. There were available for immediate service some 3,400 combat planes, with about 3,600 pilots and 43,000 ground personnel. The training program had set a goal of 6,000 pilots and 60,000 personnel, and this was being carried out with considerable enthusiasm. Italy had a natural bent for air power, with its traditions of Leonardo da Vinci, one of the world's greatest inventors; Gen. Douhet, who after World War I insisted that air power should have complete authority in its own realm; and Guidoni, the genius in aeronautical research and design. One of Il Duce's first moves was the founding of Guidonia, a city near Rome completely devoted to aeronautical research and experiment for which no expense was spared in providing the latest scientific equipment, following the lead of the Germans at Adlershof (near Berlin). However, there was a fatal weakness. The above factors, true in themselves, tended to obscure the fact that Italy had the lowest war potential of any country in Europe. She lacked the raw materials vital to modern warfare, and her heavy industry and industrial equipment generally was weak. Thus many of the Italian aircraft were made of fabric-covered plywood and steel tubing.

The Regia Aeronautica learned some lessons in the Ethiopian campaign which resulted in technical improve-

U.S. navy fighter pilots in the ready room of an aircraft carrier somewhere in the Pacific during 1945

ments of their fighters and bombers. When civil war broke out in Spain, Italy, convinced that Russia's activities on the side of the loyalists threatened to become a menace to all Europe, heavily supported Franco. Large numbers of Fiat CR-32 biplane fighters (550 h.p. engine, top speed 240 m.p.h.) and obsolescent Savoia-Marchetti and Caproni bombers were sent in first, to be followed by some of the newer matériel as it came along. This included the Fiat CR-42 (still a biplane); Fiat BR-20 medium bomber; Breda 82 light bomber; Breda 88 fast, medium bomber; Savoia-Marchetti SM 79-B tri-motored bomber; and the Macchi C-200 monoplane fighter, good for about 315 m.p.h. Altogether Italy sent an estimated 2,000 military planes to Franco. Apart from this considerable numerical help, which certainly was a factor in his final victory, it cannot be said that the Italian planes or pilots made a particularly impressive showing against the Russian, United States, English and French airmen who in one way or another and in whatever equipment happened to be available, fought against them.

In the matter of aircraft engines, the Italian Fiat and Piaggio air-cooled radials of 7, 9 and 14 cylinders were roughly equivalent to similar types made in England, France and Germany. Italian V-type liquid-cooled engines were about equal to the French Hispano-Suiza, but not up to the German Daimler-Benz DB-600, Junkers Jumo-211 (both inverted V's), or the British Rolls-Royce Merlin.

Great Britain.—Under the stimulus of storm warnings of disaster ahead, the British government had made plans in 1936 for an air force second to none. Germany and Italy had made no secret of their belief that air power would be the determining factor in establishing a new balance of military power and international influence. Great Britain made her plans accordingly, in terms of the whole empire. India, the dominions and every possession were called upon to contribute to the air strength which was believed vital under the international conditions then existing. The air ministry announced that the expenditures for fiscal 1937 would be more than double those for

1936. The program included increase in bomber squadrons for long-range operations, combat squadrons for the fleet air arm, expansion of home defense with fast fighter squadrons, building up of reserve supplies including gasoline, development of aircraft and engine manufacturing facilities on a mass production basis, and increase of trained air force personnel throughout the empire. For various reasons, however, this ambitious program was far from realized within the first year or, two, parts of it not becoming effective until 1939. The main reason was undoubtedly interservice rivalry and the traditional top-side conviction of the superiority of the royal navy and the redoubtable army. Regardless of what the rest of the world did, England would march and sail to war and only defend itself in the air.

In Jan. 1937 the royal air force had a total of 4,000 planes, though probably fewer than 1,000 of these were first-line planes fit for modern air combat. The home defense forces had 1,400 planes in service, with 1,000 in reserve. The fleet air arm had about 500, including reserves. Royal air force units outside the United Kingdom had some 600 combat planes, including reserves. The air forces in India and the dominions had a total of 500 planes, including reserves. Total air force personnel in the British empire was 52,000, with 4,000 qualified pilots.

English aircraft engines were at this time among the best in the world. The famous Bristol company had the Mercury and Pegasus 9-cylinder poppet-valve engines of 650-700 h.p., and three of their specialized sleeve-valve engines, the 9-cylinder Perseus (850 h.p.) and the 14-cylinder two-row Taurus (950 h.p.) and Hercules (1,100 h.p.), all air-cooled radials. Rolls-Royce was turning out liquid-cooled V-engines, including the Kestrel (650 h.p.), with the world-famous Merlin (then rated at 900 h.p.) coming into production as the power plant of the recently-designed Hurricane and Spitfire. The Merlin was the standardized development of the specially souped-up

Bristol also had a fast new medium bomber, the Blenim, slated to replace the Fairey Battle. Handley-Page had twin-engine Hereford and Hampden, and Vickers the ellesley and Wellington, both of geodetic construction isket weave of metal strips and fabric). Another imrtant model coming into the picture at this time was e four-engine flying boat Short Sunderland. In 1934 the ministry had decided to abandon the biplane fighter favour of a heavily armed monoplane fighter. R. J. tchell of Supermarine, designer of the Schneider cup aners, came up with the famous Spitfire Interceptor, t-flown in 1936, in production in 1938 and in squadron vice in 1940. Sydney Camm, chief designer of Hawker craft, designed the Hurricane fighter, which came into vice in 1938, became the backbone of R.A.F. activities France in the spring of 1940 and largely saved the day the battle of Britain.

In the expansion of the royal air force, which followed revelation of what the luftwaffe had been doing, three hnical decisions of far-reaching importance were made: unprecedented eight Browning .303 machine guns were used in the wings of the Hurricane and Spitfire, enling them to pour a terrific fire into their opponents; a power-driven gun turret was planned for all British ig-range bombers and adapted for some current models; British production was reinforced by the purchase of eral types of U.S. aircraft and engines.

Unlike the air forces of France, the U.S.S.R. and the lited States, the royal air force after 1919 (when the royal ng corps and the royal naval air service were united) had an arm totally distinct from the army and the navy l independent of either. It was made up of men who re not soldiers and not sailors but airmen. In 1937, wever, as a result of high pressure from the admirals, fleet air arm of the royal navy was created and put der the admiralty. This consisted of aircraft flown from riers, used in naval reconnaissance and fleet operations. late as 1939 its aircraft models were largely obsolete ample, the Fairey Swordfish biplane, speed 154 m.p.h.), leficiency partly corrected early in World War II by the lition of U.S. navy models such as the Grumman Mart-(Wildcat, F4F).

Inited States.—By Jan. 1, 1937, only a bare beginning I been made in the matter of U.S. air power. The ny air corps had on hand about 1,500 military aircraft all types, of which more than 500 were obsolete and 700 re obsolescent. An additional 1,000 aircraft were on ler to meet the goal of the Baker board report (1934) "2,320 modern, serviceable planes, to be attained not er than June 30, 1940." Top strategic thinking (except ong army airmen) was that owing to the favourable ographic position of the United States, the navy was t line of defense and aeroplanes were only useful for operation with ground and sea forces and for defense uinst actual air attack. This prevailing point of view ided to clip the wings of U.S. army aviation. The air ps on June 30, 1937, consisted of about 1,300 officers and 000 enlisted men. On this same date the navy's air force 1 927 service and 195 obsolescent aircraft on hand and) new aircraft on order. A five year goal was to bring : authorized total to 1,910 planes in 1942. Besides the ler aircraft carriers, "Saratoga" and the "Lexington," : "Ranger" had been commissioned in 1934, and the ger sister carriers "Yorktown" and "Lexington" in 1936. A good foundation for air power had been laid with establishment on March 1, 1935 (based on appoint-

ments in Dec. 1934), of the general headquarters air force, commanded by Maj. Gen. Frank M. Andrews. The G.H.Q. air force comprised all combat units of the air corps, with general headquarters at Langley Field, Va., and three wings with bases on the Atlantic and Pacific coasts and the south-central part of the United States. It was here that U.S. air doctrines, following closely some of the dynamic ideas of both Gen. Mitchell and the Italian Gen. Douhet, crystallized, and new applications were developed. Andrews, Hugh J. Knerr, Henry H. Arnold, Carl Spaatz, George Kenney, Harold L. George and a few others contended that the long-range heavy bomber was the keystone of air power. To destroy vital industrial targets back of the enemy front lines or to attack a hostile fleet hundreds of miles out to sea meant that bombers had to have not only range, but speed, defensive armament, precision navigational instruments and bombsights and a bomber crew which could work together as a team. This philosophy was embodied in the development of the four-engine Boeing B-17 Flying Fortress, long-range daylight bomber, a type which was to be proved as the air power weapon par excellence of World War II.

Other ideas of these airmen included the conception of attack aviation, close co-operation with ground forces as an air-ground team, not simply support of ground forces, such as artillery support. Also the thought that air power should be as nearly as possible self-sustaining by means of a fully developed air transport service to bring engines, propellers, parts and supplies to forward bases as rapidly as possible.

The 1937 crop of air corps planes consisted of stubby Seversky P-35 and Curtiss P-36 fighters, with a few dozen obsolete Boeing P-26s still around; the standard medium bomber was the Martin B-10 and B-12, with the Douglas B-18 (developed from the DC-2 airliner) coming in; the first of the Boeing B-17s, the world's only four-engine daylight bomber, was accepted; attack planes included the Northrop single-engine A-17 and the Curtiss twin-engine A-18. Navy fighters included the Grumman F3F and Curtiss F2C (biplanes); scout bombers, Vought SBU-2 and Curtiss SBC-3 (biplanes) and Vought SB2U low-wing monoplane; Douglas TBD Devastator was a torpedo bomber and Consolidated PBY a patrol bomber; main scout observation type (with floats, catapulted from battleships and cruisers) was the Vought OS2U Kingfisher. Practically all army and navy models were powered by air-cooled radial engines by Wright and Pratt & Whitney, ranging from 750 to 1,000 h.p. The Allison liquid-cooled engine was under development.

On June 30, 1938, air corps strength stood at about 19,200, with 1,300 officers. About 500 military pilots per year were being turned out at Randolph and Kelly fields, Texas, and about 1,000 aeroplane and engine mechanics at Chanute field, Ill. In Sept. 1938, the month when Hitler held up Europe at the Munich conference with his threat of air power, Brig. Gen. H. H. Arnold became chief of the U.S. air corps. In view of the storm clouds over Europe in April 1939, an air corps expansion bill was passed in congress, authorizing the purchase of 6,000 aeroplanes, increase of officers to 3,200, enlisted men to 45,000, and a pilot training program with a peak of 20,000 per year, to be reached in stages, with a goal of 24 combat groups. Also, funds were appropriated for constructing large air bases in the four quarters of the country, dividing the U.S. into four air districts. In Aug. 1939, 30th anniversary of the acceptance of the first army aeroplane, the

air corps had a series of demonstrations resulting in the capture of several international records for speed, altitude and payload of heavy bombardment aircraft, using B-17s and the huge Boeing B-15 (only one built).

U.S. naval aviation stepped up its activities during 1938 and 1939, developing new types of fighters and scout-bombers (including the famous Grumman F4F Wildcat and Douglas SBD Dauntless, which were to prove the backbone of the early months of the Pacific war), and increasing the training program of pilots and technicians. Aircraft carriers took an increasingly prominent part in fleet manoeuvres.

China.-When Japan began the "Chinese incident" in July 1937, China's air force consisted of about 600 obsolescent aircraft. Generalissimo Chiang Kai-shek almost from the start had a high appreciation of air power, and he made Madame Chiang secretary general of the Chinese air force. In 1932 China's financial expert in Washington, D.C., Dr T. V. Soong, engaged Col John J Jouett, disciple of Gen Mitchell and West Point classmate of Gen. Spaatz, to build up a modern air force for China. With a small group of U.S. fliers and hearty co-operation from the generalissimo and a dynamic little Chinese air officer who had learned to fly in Russia, Maj. Gen. Peter T. Mow, Jouett drastically overhauled the Chinese air force. He established a new Central Aviation school at Hangchow, and by 1933 the school had 250 modern combat planes and 350 Chinese pilots trained to the exacting standards of the U.S. army air corps. The Japanese brought such heavy pressure to bear that by the end of 1934 the Jouett mission was terminated, but not before it had seen the establishment of indigenous aircraft factories for turning out planes, though no engines.

From 1935 the Chinese were forced to buy up a conglomeration of whatever foreign planes they could, including Italian Bredas, Fiats, Savoia-Marchettis, German Heinkels and Junkers, British Bristol Bulldogs and Armstrong-Whitworths and American Boeings, Martins, Northrops and Vultees. Curtiss Wright's export company for the far east, Intercontinent corporation, had set up an aeroplane factory in China. This corporation was acquired by William D. Pawley, who sent Charles Day to China to manage the factory. When the Japanese struck in 1937, Madame Chiang asked Day to remain and help the national government in aircraft production. His first job was to move the Pawley factory into the interior of China, and during the next four years it was moved eight different times to avoid being blasted by the Japanese bombers.

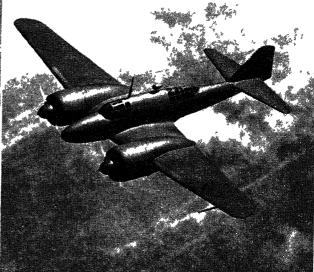

In 1937 the Chinese made another effort to revive their air power with US help. A US. air corps captain, Claire Chennault, an expert in aerial tactics, had retired on account of deafness. Two of his associates who had been in China helping to train combat pilots recommended Chennault to the generalissimo, who promptly brought him to China. However, it was too late to whip up the semblance of an air force before the Japanese attacked, and within a few weeks China's air force was nearly obliterated. For the next three years, except for a few courageous counterattacks by Chinese pilots with locally built Curtiss Hawks, a couple of Martin 139 (American B-10) bombers and a few Russian Chato, Rata (Mosca) fighters, and SB bombers, the air war in eastern Asia became a gigantic slaughter of Chinese civilians by the bombs and machine guns of the Japanese air force. All this time, however, Chennault was observing, studying and planning for the day when China would strike back.

Japan.-Like the air forces of the United States, France and several other countries the Japanese army and navy each had its own aviation. In 1937 the Japanese imperial army air corps had about 940 combat planes, while the Japanese navy had about 480 combat planes with the fleet and 580 at shore stations. This represented a grand total in both services of about 2,000 combat planes, many of them obsolete. Less than one-third of these were bombers, a deficiency made up later. The 2,300 pilots and 22,000 ground personnel were about evenly divided between the army and the navy. The headquarters air force of the army aviation service was closely patterned after the U.S. army G.H.Q. air force. It was the striking force of army aviation, and was charged with the defense of Japan's coasts and its outposts in Manchuria. One brigade (similar to wing) was based at Gifu, a second at Kwainei, Korea, and a third in Formosa. The navy was making every effort to increase the number of carriers, and in July 1936 laid the keel for the new aircraft carrier "Hiryu," of 10,500 tons. By 1938 army air squadrons were to be increased from 32 to 38, and navy's 40 to 52. The immediate concern was home defense, and the fear that in any largescale campaign the chief industrial and political centres of Japan might be subjected to destructive air raids. The imperial army air corps also had to be built up for the campaign in China which, it was thought, might prove long enough to deplete the air forces and make Japan vulnerable to attack by Russia. Naval aviation needed to be strengthened to maintain communications and support Japan's far-flung lines of conquest.

The year 1936 saw a six-year army reform plan instituted, with the militarists more firmly in the saddle than ever. Pilot-training was stepped up, and aircraft production increased. From the outset Japan had resorted to the copying of certain models of foreign planes and engines or building them under licence, in some cases making ingenious improvements. However, the great weakness was a lack of the raw materials and processed materials required to reproduce United States, German or Italian planes. This meant danger of structural failure of their planes in combat, an eventuality which came to pass with great frequency in the Asiatic-Pacific war which lay ahead. From early 1937, as a result of a treaty with Germany, production of planes and engines from Japan's own aircraft factories was slightly augmented by shipments from its axis partner in the west.

Air War in Europe, Early Stages.—Germany.—During 1938 the German air force had been organized territorially into three air fleets, or Luftflotten. Headquarters of No. 1 was at Berlin, under Albert Kesselring; No. 2 was at Brunswick, with Felmy commanding; No. 3 was at Munich, under Hugo Sperrle. After the political conquests of that year, fleet No. 4 was organized with H.Q. at Vienna, commanded by the Austrian General Alexander Loehr. At the start of the Polish campaign in Sept. 1939, the luftwaffe had a first-line strength of some 5,000 aircraft. Air fleet No. 1 with advanced H.Q. in East Prussia and No. 4 with advanced H.Q. in Breslau were used in Poland. The bomber force had about 700 aircraft, including He-111K, Do-17S and a few Ju-26K, the latter not used as a bomber again. The newer, faster Ju-88s were not used in Poland. There were about 400 fighters, mostly Me-109E (improved over the original version by use of the Daimler-Benz 1,150-h.p. engine), some twin-engine Me-110s and a few biplane He-51s, henceforth used only as a fightertrainer. There were 150 Ju-87 stukas, 350 reconnaissance planes and 250 Ju-52 transports. Altogether between 1,800 and 1,900 aircraft, against a Polish air force of some 500

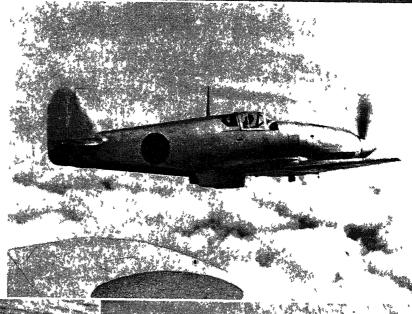

Above: Mitsubishi Zeke 52 (Zero), Japanese carrier fighter plane: maximum speed 354 m.p.h.; cruising speed for maximum range 152 m.p.h.

Above, right: Dinah 3, Japanese light bomber and reconnaissance plane with a maximum speed of 407 m.p.h.

Right: Tony, Japanese fighter plane with a top speed of 361 m.p.h.

Below, left: Sally 2, Japanese medium bomber capable of 294 m.p.h.

Below, right: Rufe II, Japanese float plane used for fighting and observation; maximum speed 345 m.p.h.

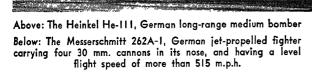

The Messerschmitt Me-109, German fighter plane with top speed in excess of 350 m.p.h.

The Messerschmitt Me-163, speedy rocket interceptor of the German air forces, with a top speed of 550 m.p.h. and a cruising speed of 250 m.p.h.

Above: Captured Junkers Ju-88, German medium bomber (with U.S. marking on tail and wings)

Below: The Focke-Wulf 190, German fighter plane with a top speed in excess of 380 m.p.h.

Following the Douhet pattern, the luftwaffe operations were in three phases: (1) destroy the Polish air force on the ground; (2) destroy in air battles any units of the P.A.F. able to engage in combat; (3) destroy the Polish ground forces means of deployment, such as rail lines, bridges, supply and ammunition dumps, communications, etc. Also (not à la Douhet) provide air co-operation for the wehrmacht wherever needed. Despite the lightning victory which practically eliminated the Polish air force in two weeks, the luftwaffe lost some 600 planes in combat with the courageous Polish fliers, besides an additional 1,500 to 1,800 through forced landings, crack-ups in taking off and discarding of planes which could not be serviced during the campaign. This was the result of a direct policy set by Milch, overruling Udet, a costly mistake which was to plague the luftwaffe more and more as the projected lightning victory failed to materialize.

After Poland the luftwaffe regrouped for the Danish-Norwegian campaign which began April 9, 1940, when Hitler invaded the two Scandinavian nations. This campaign was a victory for the lultwaffe as a means of an transport rather than as a strategic or tactical unit in air combat, with the old Ju-52 transport the most effective plane in ferrying clouds of German troops over the helpless head of the British navy. In all, some 800 planes were used, of which half were long range bombers, including the new and effective Ju-88. There were at least 100 to 150 floatplanes and flying boats, including He-115, Dornier and Blohm & Voss models. Especially effective were the converted Focke-Wulf 200 Condor four-engine transports used for armed reconnaissance and antishipping patrol with a 1,000-mile radius of action and endurance of 12 to 15 hours. This planned use of air transport and antishipping operations was an example of the adaptability of the luftwaffe squadrons and the value of the special training given during the winter of 1939-40. The important strategic lesson of the Norwegian campaign was that land-based aircraft could prevent superior sea power from exerting itself if naval units ventured to operate within convenient bomber range.

The role of the German air force in the campaign against the Low Countries and France was that of cooperation with the wehrmacht, with all air actions within the framework of the main ground strategy, as in Poland. On May 10, 1940, German armies crossed the Belgian and Dutch borders, and the luftwaffe launched an immediate and highly successful air offensive against the airfields of the Netherlands. In most cases the Dutch planes were never able to get off the ground. The German armies broke through, heavily supported by dive bombers, the luftwaffe even providing air protection for the rapidly advancing tank columns. Some 3,500 to 3,800 combat aircraft, or nearly four-fifths of the total front-line strength of the German air force was thrown into the campaign. The cream of luftwaffe fighter and dive-bomber pilots was available at that time. Aircraft types included 1,400 long range bombers (Ju-88, He-111K, Do-17S); 400 dive bombers (all Ju-87s); 1,200 fighters (900 Me-109s, 300 Me-110s); 600 reconnaissance aircraft (Do-17 and He-111 for long range strategic reconnaissance, Henschel 126 for tactical and the agile Fieseler Storch as a liaison plane for communications, etc.); some 500 Ju-528 provided the German squadrons with tactical mobility. Despite heroic resistance by advance R.A.F. units, aided to some extent by French pilots, the luftwaffe had things more or less its own way. The last wings flew back to England on June 15, 1940, the day after the nazis marched into Paris.

Up to that time the luftwaffe had had no occasion to meet a first class air force in air combat and to try out Douhet's classic second principle: destroy in the air the enemy planes which had not been destroyed on the ground. During the Dunkirk evacuation (May 27-June 4, 1940) the German air force had its chance, but to the dismay of its leaders and its pilots, received the mauling of its life. On May 29 R.A.F. fighter group 11 left its bases in England to engage the luftwaffe before it could break through to Dunkirk and create a genuine catastrophe. Hurricanes, Spitfires and Boulton-Paul Defiants pitched into a much larger German force of some 1,500 aircraft, mostly Ju-87s and Me-109s, and destroyed at least 300 as against 100 R.A.F. losses. They had the edge in speed, manoeuvrability, fire power and pilot training. It was a decisive defeat.

In Germany, however, the luftwaffe was riding high because of its spectacular successes with the German army in the Netherlands, Belgium and France. After this sustained sprint a breather was needed, and this lack of staying power was the luftwaffe's most glaring deficiency; inability to attack England shortly after Dunkirk probably lost the war for Hitler. The British were given time to organize their air defense, including their chain of radio-location (radar) stations. During the battle of Britain these stations enabled fighter controllers to detect the direction, strength and height of German air attacks, permitting the R.A.F. to use their Hurricanes and Spitfires very economically, and cut fighter patrols to a minimum. According to German communiqués the all-out air attack on England started Aug. 10, with the entire luftwaffe of 3,500 first-line aircraft, with 50% to 75% reserves available.

The first phase lasted from Aug. 10 to 18, and consisted of great numbers of Ju-87s with fighter escort (a lesson learned at Dunkirk) bombing convoys, shipping, ports, coastal airfields and installations, while the longer range Do-17s, He-111s and Ju-88s attacked fighter aircraft factories and radio-location stations. However, the R.A.F. pilots knocked down 697 German planes against 153 losses, and the German objectives were not realized. Goering pushed on to the second phase, which ended Sept. 5, and aimed at destroying inland airfields, factories, railroads, communication systems, etc. Despite heavier fighter escort German losses were 562, British 219 (with 132 pilots parachuting to safety). Again, the objectives were not realized, but in desperation Goering threw everything into the third phase, a relentless bombing of London, which lasted until Oct. 5. In 38 daylight and 8 night attacks the luftwaffe lost 440 planes, the R.A.F. 58. During the rest of October the final phase took place, featured by small formations of Me-109s and Me-110s dropping small loads of bombs in hit-and-run raids at night. The luftwaffe had lost. At least 2,375 planes down in combat, half as many again in operational losses, and thousands of well-trained pilots and other crew members lost. Reasons for the failure were many. Chief among them was the lack of true understanding of air strategy, which called for a concentrated attack on English fighter airfields, using fragmentation bombs and ignoring all other targets. On the technical side, the terrific fire power of the eight-gunned Hurricane was more than a match for the fast but lightly armed German bombers, and the similarly armed, speedy Spitfire outfought the German fighters.

The scene then shifted to the Mediterranean. Toward

26!

the end of 1940 the luftwaffe set up an air headquarters in Rome and an operational command in Sicily. The main local objective was to aid the Italian air force in neutralizing Malta as a base for shipping passing through the Mediterranean. This would compel the British to reroute their convoys to the near east via the much longer route around Africa.

Except for April and May 1941 the luftwaffe in the Mediterranean was never very formidable. It consisted of the 10th air corps, drawn from Norway and western Europe, and included some 350 combat aircraft-150 Ju-88s and He-111s, 150 Ju-87s, 40 Me-110s and about a dozen long range reconnaissance aircraft. In the spring of 1941, 50 Me-109s were added. Despite heavy attacks Malta held out, although shipping became a costly venture. The capture of Crete in May 1941 by glider-borne forces was a remarkable operation. The German air force, operating in close support of Rommel's give-and-take battles in North Africa, varied between 200 and 300 aircrast of the current types. When Yugoslavia entered the war on the Allied side, the luftwaffe came up with a quick redistribution of forces, doubling the Balkan air force from 500 to 1,000 aircraft within a week by drawing from western Europe. However, in June, just as the British position in the middle east seemed particularly grave with Erwin Rommel at the Egyptian border, Hitler invaded the U.S.S.R.

For a combination of reasons, and despite Goering's warning, Hitler had made this decision, and the Russian campaign began on June 22, 1941. After the battle of Britain was lost, airfields in Norway, Finland, Poland and Rumania were prepared for receiving German air force units. By the end of the Balkan campaign in June the luftwaffe had some 3,000 aircraft on the eastern front, representing about two-thirds of its current first-line strength. Three of the five Luftflotten, No. 2 (from the Low Countries), No. 4 (from the Balkans) and No. 5 (from Denmark-Norway), plus the entire tactical support organization which enabled the German armies to make their lightning drives in the west, were there, together with Germany's top air force commanders, including Albert Kesselring, Alexander Loehr, Wolfram von Richthofen and Robert Ritter von Greim. The plan was for an all-out attack to destroy the Red air force on the ground, smash through and crush all Russian resistance within six months at the most. The Russians failed to co-operate.

German aircraft types included 1,000 long range bombers (He-111s, fewer Do-17s, more Ju-88s), 400 dive bombers (Ju-87s), 900 fighters (750 Me-109s, 150 Me-110s), and 700 reconnaissance planes. This total of 3,000 for an 1,800-2,000 mile front meant spreading the tactical support far too thin, and precluded anything like sustained strategic air operations against vital industrial targets behind the Russian lines. Owing to the vast Russian distances a fleet of 500 Ju-52s was constantly required to maintain operating efficiency in the forward areas.

By a sudden surprise attack, heavy losses were inflicted on the Red air force in the early days, although Russian dispersal in both width and depth prevented these losses from becoming disastrous. The inferiority of the Russian fighter aircraft at this early stage, plus the far greater combat experience of the German pilots meant that the luftwaffe gained air mastery and paved the way for the rapid progress of the German armed forces through the Baltic states, Poland, White Russia and the Ukraine. By October, however, the luftwaffe was panting for breath, and with

the failure to take Moscow and the coming of winter, Hitler called for a lull. Taking their own winter in their stride, however, the Russians counterattacked.

U.S.S.R.-Seven days before Hitler invaded Poland he entered into a secret nonaggression agreement with Russia, the Ribbentrop-Molotov pact. Moscow undoubtedly knew Hitler's ultimate intentions, but this gave a breathing spell to build up soviet defenses. As soon as the nazis had conquered Poland (Sept. 17, 1939) the soviet armies moved into Poland from the east, and within two days raced across nearly half of Poland to the Russian 1918 border, cutting off Hitler from the rich oil wells of Galicia and blocking the road to Rumania. In October Moscow made certain demands on Finland, most of which were met, but later the negotiations were broken off, and on Nov. 30, 1939, Russian planes bombed Viipuri and Helsinki. The Finns resisted stoutly and held the Russians in the north, but in January a direct assault on the Mannerheim line was made, and with a more effective use of the Red air force, a break-through was achieved in March, Finland surrendering on March 12. This did not help Russia in world opinion, but it did provide a buffer in the north which undoubtedly saved Leningrad a year or two later. Fifteen months after Finland gave up, Hitler attacked Russia.

The war between Germany and Russia was primarily a land war, with the air forces on both sides used almost wholly in support of army operations. Probably nobody outside Russia knew how many aircraft the Red air force had in June 1941, but it may well have been 3,000-4,000 in first-line aircraft, many of them obsolescent, with 50% to 75% in reserve. All aircraft, engine and accessory production was in state factories under the Glavavioprom (central directorate of aeronautical industry). Estimated production was 750 to 800 planes per month, some of the factories already located beyond the Ural mountains.

The bulk of the fighters were Spanish Civil War veterans, including the I-15 biplane, improved I-153, and the stubby I-16 and I-16B low-winged monoplane (I is for Istribuitel, or destroyer). Top speed ranged from 250 to 295 m.p.h., which was also the speed bracket of the current medium and attack bombers, the SB-2 and PE-2. During the first few months all these models suffered heavily at the hands of the new Me-109F with its top speed of 380 m.p.h. The new soviet air force fighters, I-18 (later designated MIG-3 after its designers Mikoyan and Gurievitch) and I-26 (YAK-1, for Gen. Alexander Yakovlieff, designer and vicecommissar of aviation) were in the 350-375 m.p.h. range, but only a few of them were in operation; this was also true of the famous IL-2 Stormovik heavily armed attack plane dive bomber, named from Sergei Ilyushin. The Russian air force was also weak in reconnaissance aircraft, relying on the SB and DB bombers (S for srednye, medium, and D for dalnye, long range), which were 50 m.p.h. slower than the widely used Ju-88 on the German side. The most effective part of the Russian air force was the groundattack forces even in this early stage, with their use of I-15 and I-153 and older biplanes in low-level attacks as fighter bombers and ground-strafing aircraft, including their use of small rocket bombs launched from rails against German tanks and other ground targets.

The Ju-87 stukas, shot out of the air in droves by Spitfires and Hurricanes over England, were expected to have a field day in Russia. However, after the first few weeks the determined Russian anti-aircraft gunners learned to speed their technique to catch them as point-blank shots in their fast 70 to 80 degree dives.

All in all, the wehrmacht and luftwaffe found they really

had a bear by the tail in the Red army and air force, and the dream of a quick victory froze up on the Russian steppes.

France.-In the spring of 1940 the French Armée de l'Air had about 600 first-line fighters, with 700 in reserve. Best of these was the U.S. Curtiss Hawk 75A, of which there were several hundred; top speed was 315-320 m.p.h. The reliability and long service span of the Wright Cyclone 1,000-h.p. air-cooled radial engines were in marked contrast to the Hispano-Suiza and Gnome-Rhone engines of French aircraft. French fighters included the Potez, Morane and Dewoitine models, with a speed range of 290 to 310 m.p.h. The principal German fighter of this period, the Me-109E, had a top speed of 350 m.p.h., was manoeuvrable, well-armed and more than a match for any of the French fighters, including the U.S. Hawks. The French pilots, however, fought with such skill that they managed to knock down several hundred German fighters and bombers in air combat. French bombers numbered about 300 with 100 in reserve. U.S. twin-engine Martin 167 (afterward called Maryland by the British) and Douglas DB-7 (later named Boston) were just beginning to trickle through. In any case the Germans had definite air superiority, which meant limited activity for the French bombers. When France surrendered, all military equipment, including planes, had to be yielded. However, Gen. Charles de Gaulle's historic call from London on June 18, 1940, was answered by numerous trained pilots. They became the nucleus of the Free French air forces under the command of Gen. Henri Valin, former chief of staff of the Armée de l'Air. They were combined with the French North African aviation corps in Aug. 1943. Besides this many individual French fliers fought with R.A.F. units in both fighter command and bomber command.

Great Britain.—As we have seen, the royal air force was a completely independent arm, co-equal with the British army and royal navy, rooted in the air ministry whose controlling authority was the air council. At the outbreak of World War II, Sir Archibald Sinclair was president of the air council and secretary of state for air; chief of the air staff was Air Chief Marshal Sir Charles Portal, later marshal of the royal air force (five-star rank). The home commands included bomber command, whose primary function was attacking strategic targets in the enemy country; fighter command, initially for air defense, but later used with great effect in short range offensive operations; coastal command was responsible for all oversea operation in close association with the royal navy, including air patrol, antisubmarine activities, convoy patrol, etc.; also training command, maintenance command, etc. Overseas commands included the middle east command under Air Marshal Sir Arthur W. Tedder; air forces in India; R.A.F. ferry command, with headquarters in Canada for ferrying U.S. aircraft across the Atlantic by air. Production of aircraft and engines was under the ministry of aircraft production, headed by Sir Stafford Cripps and taken over in the spring of 1940 by Lord Beaverbrook, at which time it was still below the wholly inadequate production of the summer of 1939

Bomber command was active in the war within an hour or two of its declaration, and within six months had built up an impressive record of "leaflet raids" and day and night photographic reconnaissance missions, which were not only valuable in themselves but served to train the most expert night-flying pilots and navigators in the world, an indispensable foundation for the great night air assaults against the Ruhr valley and other vital objectives which began two years later. Besides these missions there

were regular bombing missions against ports, bases of mine-laying aircraft, etc. Bombers available were the obsolescent Fairey Battles, Handley-Page Hampdens, and Armstrong Whitworth Whitleys, with the Bristol Blenheims and Vickers Wellingtons; speed range of this group was from 240 to 275 m.p.h.; bomb loads from one to two-andone-half tons. In 1941 the advent of the four-engine Short Stirling and Handley-Page Halifax, which carried eight and six tons of bombs respectively, added greatly to the weight of bomber command's attack, as more and more trained crews began to be available from the great British commonwealth air training program which had been set up in Canada. Main types of targets included aircraft factories, factories making aluminum, oil-producing plants and communications (rail junctions, bridges and canals). In six months from April to Sept. 1941, some 20,000 tons of bombs were dropped on such targets.

Bomber command also used fighter-escorted Blenheims in day attacks, especially against shipping, took an active part with coastal command in the battle of the Atlantic and carried out an extensive mine-laying program to help keep an airtight blockade against Germany. In Jan. 1941 Blenheims also began a long campaign against enemy airfields on the French coast, which later included Hurricane, Whirlwind and Typhoon fighter bombers, and U.S. built Bostons and Mitchells.

During the first year of the war coastal command flew 13,000,000 mi. in 106,000 flying hours. Some 160 attacks were made on U-boats, and air escorts were provided for more than 50,000 ships in convoy. Big Sunderland flying boats were the mainstay, plus Avro Anson bombers for patrol. During 1940 the first of the U.S. built Lockheed Hudsons went into operation, performing with noteworthy effect. Converted from the Lockheed Electra 12-passenger fast transport, and with the addition of a power turret, the Hudson surprised everybody with an amazing record of reliability and versatility.

Because the field of battle was out of range of fighters designed primarily for the defense of England, fighter command was unable to prevent the Germans from winning the battle of Norway by a shuttle service of transports across the Skagerrak. When the Germans invaded the Low Countries on May 10, 1940, the R.A.F. had six Hurricane squadrons of the air component, four with the British expeditionary force and two with the French. That same day two more joined the British and the next day one more squadron joined the French, or some ten fighter squadrons (120 Hurricanes and pilots) against the massed might of the luftwaffe. A second force, known as the advanced air striking force (A.A.S.F.), consisted of two squadrons of Hurricanes, eight of Battles (light bombers) and two of Blenheim medium bombers. The French air force worked with this A.A.S.F. Within two weeks, however, all R.A.F. aircraft except three Hurricane squadrons of the A.A.S.F. had been withdrawn to England; so rapid had been the enemy's advance that available airfields had dwindled to a handful. We have seen how with air supremacy over the channel, fighter command won over Dunkirk, whereas without it the powerful Royal navy lost in Norway. We have also seen how a quickly reorganized fighter command, aided by radio-location, some telling attacks by bomber command and constant vigilance by coastal command, turned the tide in the battle of Britain, decisively defeating the luftwaffe. This may be reckoned one of the turning points of history, when so much was owed by so many to so few.

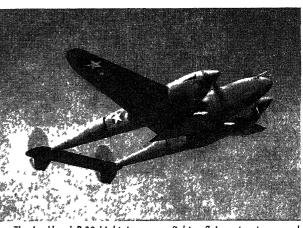

North American P-51 Mustang, army fighter plane with a maximum speed of 435 m p.h.

B-26 Martin Marauder, army medium bomber

The Douglas A-26 Invader, lightweight attack bomber of the U.S.A.A.F. with a top speed of 355 m.p.h. which went into action in 1944

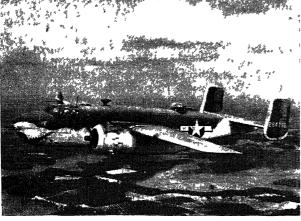

The Lockheed P-38 Lightning, army fighter flying at a top speed of 414 m.p.h. and equipped with zero-type 14 rocket launchers for carrying 5-inch rockets

Below: The B-24 Liberator, heavy bomber of the U.S.A.A.F. memorable for its strategic bombing of the Ploesti oil fields of Rumania in 1944

When the Germans switched to night hit-and-run attacks, fighter command had to improvise night fighter defense. At first it was like a needle in a haystack, but as radio-location improved, and especially after a lightweight AI (aircraft intercept) radar set could be fitted in the night fighters, successes mounted. On account of their endurance Blenheims were used first, then the faster single-engine Hurricanes and Defiants, followed by twin-engine Douglas DB-7s called Havocs, and the 330-m.p.h., powerfully-armed Beaufighters. The last mass night raid was May 10, 1941, when 33 German bombers were shot down out of 250, with as many more seriously damaged.

After the collapse of France in June 1940, Italy declared war and prepared to attack Egypt from Libya. The R.A.F. had about 170 aircraft, mostly obsolete, in the middle east, against 400 modern fighters and bombers of the Italians; the R.A.F. also had about 85 more in East Africa against Italy's 110 bombers and 60 fighters. Technically outclassed and outnumbered, the western desert air units (five squadrons of Blenheims, Gladiators and Lysanders) had a threefold task, to maintain close co-operation with the land forces, to destroy and cause confusion among enemy vehicles and personnel and to maintain an offensive against enemy supply bases, airfields and sea communications. By November some 175 additional aircraft arrived, more Blenheims, Gladiators and Lysanders, two squadrons each of very welcome Hurricane fighters and long range Wellingtons for night bombing. Before the December offensive, casualties were heavy as the Italian fighter force outnumbered the R.A.F. four to one. Sir Archibald Wavell, however, advanced 400 mi. to Bengasi in 63 days against a neutralized Italian air force, some 1,100 disabled Italian planes being counted by the advancing British troops. In the spring the R.A.F. middle east was widely dispersed (Africa, Greece, Malta and Iraq), Malta was largely neutralized and Gen. Rommel was able to ferry an army across the Mediterranean. Pushing rapidly on, he by-passed Tobruk, but was stopped at the Egyptian border in June 1941.

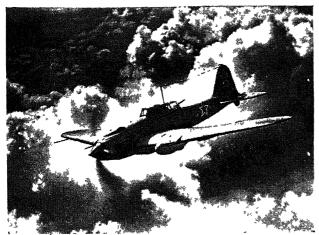

Italy.—With the imminent collapse of French resistance in June 1940, Mussolini saw the realization of his dream of building a great Italian empire in Africa and making the Mediterranean an Italian sea. After he declared war on June 10 planes of the Regia Aeronautica based in Sicily and southern Italy launched attacks against Great Britain's key base of Malta and prepared an attack against Egypt. The Italian navy, though not a match for the British, was a formidable enemy in the Mediterranean because the royal navy was widely dispersed for home defense and Atlantic life line convoy duty. On Nov. 11, 1940, however, the fleet air arm delivered a crushing blow against the Italian fleet. A mixed force of obsolete Swordfish bombers and torpedo carriers with a fighter escort of Gladiators and Fulmars took off from the "Eagle" and "Illustrious" and sank or heavily damaged three battleships, two cruisers and two auxiliary vessels.

In October Mussolini launched his attack upon Greece, and the R.A.F. sent a limited number of aircraft to help against the Italians, occupied Crete and set up an air base there. As in Africa the Italian aircraft and pilots proved no match for the British, and during February and March lost heavily in several engagements. The chief reason for the eclipse of the Italian air force was the decisive superiority of the British fighter squadrons, equipped with eightgunned 335-m.p.h. Hurricanes. The best the Italians could muster were the Fiat G.50 Falcho (falcon), top speed 290 m.p.h., and the 305-m.p.h. Macchi G.200 Saetta (lightning); both were armed with two 12.7-mm. (.50-cal.) and two 7.7-mm. (.30-cal.) machine guns, and were powered by Fiat

850-h.p. radial engines. The Reggiane Re-2000 with Fiat 1,100-h.p. engine and speed of 330 m.p.h. was coming into service in early 1941, but not in sufficient numbers to help materially. (Developments of the Italian air force subsequent to June 1941 are treated under the narrative of the luftwaffe in the Mediterranean.)

United States.—During 1940 as the emergency became more critical, the U.S. army air corps expansion program moved rapidly forward. After the Germans had swept through the Low Countries and France, spear-headed by air power, the president called for an air force of 50,000 planes and an annual production capacity of that amount. (Almost 48,000 were produced in 1942, and about 86,000 in 1943 and more than 96,000 in 1944.) By June 30, 1940, an immediate goal had been set-54 combat groups, 10,000 officers, 15,000 flying cadets, 150,000 enlisted men and 14,000 aircraft of all types. At that time there were 16 skeleton groups and wings, and about 50,000 officers and men. To train the large number of technicians requiredaircraft and engine mechanics, radio men, armourers, etc., three great technical schools were set up at Chanute field and Scott field, Ill., and Lowry field, Colo. Three flying training centres were established-Randolph field, Texas, Maxwell field, Ala., and Moffett field, Calif. A number of carefully selected civilian schools for primary flight and aeroplane engine mechanics training were brought into the picture for the new program of 7,000, then 12,000 pilots per year, and 30,000 aeroplane mechanics, plus bombardiers and navigators for heavy bomber air crews. All this training was under the commanding general of the G.H.Q. air force, which by the end of 1940 had four main district headquarters in the four corners of the land; these later became the 1st, 2nd, 3rd and 4th air forces. To provide the necessary bases for the 288 squadrons authorized by congress, the air corps began a great building program in the United States, with a similar expansion in the Canal Zone, Newfoundland, Alaska and Hawaii.

In the spring of 1941 a major reorganization of what had been the U.S. army air corps after 1926 took place. In April 1941 Robert A. Lovett was appointed assistant secretary of war for air. He, more than any other individual, was responsible for convincing the president and the secretary of war of the prime importance of the heavy bomber as a war-winning strategic weapon, and for establishing the Boeing-Douglas-Lockheed B-17 program, and the Consolidated Vultee-Ford-Douglas-North American B-24 program, which during the first seven months of 1944 was turning out between 1,250 and 1,500 big four-engine bombers per month. In June 1941 the war department announced the creation of the army air forces as a semi-autonomous unit with: (1) H.Q. army air forces; (2) the air force combat command; (3) the air corps; and (4) all other air units. The HQ. AAF in Washington included Maj. Gen. H. H. Arnold as chief of the AAF, with a separate air staff organized on the lines of the general staff, of which Brig. Gen. Carl A. Spaatz was chief. The air force combat command was the striking force, a logical outgrowth of the G.H.Q. air force, and was divided into four complete air forces covering the entire continental United States. Its chief was Lt. Gen. Delos C. Emmons, with headquarters at Bolling field, Washington. The air corps, headed by Maj. Gen. George H. Brett, was the arsenal of the AAF from which flying equipment and trained personnel were drawn, and was also charged with research and development of military aircraft and related equipment, and ferrying planes from the factories. The other air units were those attached

The IL-2 Stormovik, soviet assault plane with a top speed of 335 m.p.h.

to the various defense commands, such as the Canal Zone, the Hawaiian department, etc.

One of the divisions of the newly created air staff was air war plans, headed by Col. Harold L. George. By Aug. 1941, this group had worked out a comprehensive air war plan which was submitted to the secretary of war and presented by the president to Prime Minister Churchill and the U.S. and British chiefs of staff at the meeting in August off the coast of Newfoundland. The plan called for the creation of an air force of more than 2,000,000 men and some 88,000 planes. (The actual peak was 2,372,272 in Dec. 1944, with 224 combat groups and 79,908 aeroplanes.) Assuming that the U.S. might be at war with Germany and Japan simultaneously, Germany as the centre of the axis system and its principal military power would have to be dealt with first, with a strategic defensive against Japan until Germany was defeated. Bases were to be developed in England and the Mediterranean for a sustained and powerful daylight bombing assault against specific targets in Germany on which its continued resistance depended, including as primary objectives the electric power system, the transportation system, the oil and petroleum system, worker and general civilian morale. Certain preliminary intermediate objectives were necessary, including neutralization of the German air force, air attacks on air bases, aircraft factories, aluminum and magnesium plants. To secure bases and maintain supplies, certain diversionary objectives were recommended such as attacks on submarine bases, surface sea craft and "invasion" bases. By and large, this air war plan turned out to be the actual U.S. air contribution to the Allied victory in Europe.

A division of office of the chief of air corps was the matériel division, headed by Brig. Gen. Oliver P. Echols, which handled on the air staff level the development and procurement of military aircraft and equipment at Wright field, under Brig. Gen. George C. Kenney. The following types and models of aircraft were in production and going into operational service by the autumn of 1941: heavy bombers, Boeing B-17D, Consolidated B-24; medium - bombers, North American B-25, Martin B-26; attack bomber, Douglas A-20B (similar to DB-7B Bostons supplied to Great Britain); fighters, Bell P-39C, Curtiss P-40B,C,D, Republic P-43A; cargo transports, Beech C-45 (light), Douglas C-47 (from DC-3), and a few Lockheed C-60s (from model 18 Lodestar). Still in squadron service were obsolescent Martin B-10 and B-12, Douglas B-18 bombers; Boeing P-26, Seversky P-35, Curtiss P-36 and a few P-40 fighters.

In 1941 Rear Admiral John H. Towers was chief of the bureau of aeronautics, U.S. navy. Some 15,000 naval aircraft were under development and procurement, with 34 naval air stations and three great naval air training centres at Jacksonville, Pensacola (Fla.) and Corpus Christi (Tex.). Seven carriers were in service, with 11 more being built. A goal of 25,000 planes and 30,000 pilots had been authorized for 1942–43.

In addition to pilots, a large number of enlisted men for air and ground crews as rated mechanics, ordnance and radiomen was required. To produce these quickly under the rapidly expanding program, two large schools for aviation ratings were established at Chicago, Ill., and Jacksonville, Fla., with a capacity of 10,500. Another 4,600 were under instruction at various air stations. Although 15,000 planes had been authorized in July 1940, as part of the president's 50,000 aeroplane program, only about 5,000 usable navy planes were on hand by Dec. 1941, as the aircraft industry did not get into its stride until well into 1942. Types included the Grumman Wildcat (F4F) fighter, Douglas Dauntless (SBD) dive bomber, Consolidated Catalina (PBY) patrol bomber, with the four-engine Coronado (PB2Y) and Martin Mariner (PBM) in production. Three important models were also under development, the Grumman Avenger (TBF) torpedo bomber, the Chance-Vought Corsair (F4U) fighter and the Curtiss Helldiver (SB2C) scout bomber. There were 41 air stations in the continental United States, not counting bases in Alaska and overseas. During 1940 and 1941 the Atlantic Neutrality patrol and extended exercises in the Pacific provided much needed operational training for the eight newly-organized patrol wings (for the coming anti-submarine warfare) and for other air units. All this became the groundwork for the most powerful naval air force in history.

China.—By the end of 1940 the Chinese air force had been almost completely knocked out. Chiang Kai-shek's government had been driven from its capital of Nanking, then from Hankow, and had been set up at Chungking, far in the interior. The Japanese air force made life miserable there by daily bombings. Claire Chennault, then a colonel in the Chinese army, kept loss of life at a minimum by an ingenious and extraordinarily reliable warning system. Chinese volunteers, with portable radios, lay hidden near the airfields in Japanese-occupied China, and reported enemy aircraft activity. Two wider circles of transmitters relayed the messages in time for protective action. As a by-product this proved to be invaluable training for the day when Chennault had some fighter planes.

An Ámerican air mission was sent to China in the spring of 1941. After a careful survey the three officers reported that China was in urgent need of modern combat planes, but that any supplied by the United States should be actually used by volunteer U.S. army air corps and U.S. naval or marine pilots, operating as an independent unit of the Chinese army. Chennault (then a brigadier general) and Gen. Mow went to the United States and quietly gathered recruits from some of the best young pilots available at army and navy training fields; they also recruited a service unit of ground crew chiefs who took an intensive course at the Allison engine plant before sailing for Burma. One hundred of the original Curtiss P-40 fighters rejected by the British as not suitable against the Me-109 were sent to China. Chennault and Mow also made provision for supplies of high-octane gasoline and .30 and .50-cal. ammunition. The men went over as civilians in comparatively small groups, were met by Chennault in Rangoon, and sent to Toungoo in interior Burma for intensive training in fighter tactics, Japanese methods, etc. while their base in western China was being prepared. Thus was born the American volunteer group.

Japan.-During the summer of 1940 Charles Day, aircraft production adviser to the Chinese government, reported that Japan had about 900 first-line combat planes in China under the imperial army air corps, with some 3,600 more distributed throughout the empire, equally divided between army and navy aviation; many of these planes were either obsolete or trainers. There were about a dozen major aircraft and engine factories, mostly on the main island of Honshu, and total production was estimated to be 300-400 per month, or about 4,000 per year. Although the army had more aeroplanes and personnel, the quality of both navy pilots and equipment was slightly better. The Japanese learned much in the air activities in China, and a good deal of practical German air force fighting "knowhow" was absorbed. All this was in preparation for the great effort which lay ahead, but which ended disastrously.

The Japanese used a rather complicated and ambiguous system of aircraft designation which consisted of four items: (1) manufacturer; (2) date of first production, using the last two figures of the Japanese year, which dates from the beginning of their empire, 660 B.C. (i.e., the Japanese 2599 is the Christian year 1939); (3) air force—army or navy; and (4) type. Examples: Mitsubishi 97 army heavy bomber (later called Sally); Nakajima 96 navy land attack bomber (later called Nell). This system was far too cumbersome for fast spotting and intelligence by U.S. forces, and the short form Mitsubishi Zero (for oo) was too confusing, as it could apply to a navy fighter, and army medium bomber or a land-based reconnaissance plane. Hence, early in the war, the air technical intelligence unit in the Southwest Pacific built up its own system, using short personal names for all known models of Japanese aircraft. Men's names were given to fighters and recco floatplanes, women's names to bombers, land-based recco planes and

U.S.-built P-63 fighter planes awaiting delivery to Russia under the terms of lend-lease. More than 5,000 of this type were flown to Russia during World War II, and 112 P-63s were supplied to the Free French Air forces

flying boats. The system was speedily adopted by all the Allies.

In the autumn of 1941 the Japanese army and navy air services had between 25 and 30 models of aircraft in operation. There were, however, six basic types, probably a leaf out of the German notebook. These were the Nakajima 97 army fighter (later nicknamed Nate, given here for convenience of identification); Mitsubishi oo Zero navy fighter (Zeke 11-navy's designations had two digits, one for the airframe, one for the engine; army's had one); Mitsubishi 97 army heavy bomber (Sally 1); Kawasaki 99 army light bomber (Lily 1); Nakajima 96 navy bomber (Nell 11); Kawanishi 97 navy flying boat (Mavis 11). Zeke (1940) and Lily (1939) were modern aircrast, but the others were four or five years old, as shown by their designations. Two other models were important at this time, the Aichi 99 navy dive bomber (later called Val 11), and Nakajima navy torpedo bomber (Kate 11), principal performers in the Pearl Harbor attack.

The Final Three Years, 1942-45.—In Nov. 1941 when Gen. Sir Claude Auchinleck launched his offensive in Libya, the German air force had about 300 aircraft in support of Rommel's Afrika Korps, including some of the new Me-109Fs. There were 100 Ju-87s, but Air Marshal Tedder's R.A.F., with gradual accessions of Hurricanes and Tomahawks (U.S. Curtiss P-40s) was beginning to pick them off in considerable numbers. The Italian air force numbered some 600 aircraft and was gradually modernized with the new Macchi 202 fighters powered with the German Daimler Benz 601 engine. The Savoia torpedo bomber force was effective against Allied shipping. Both the luftwaffe and the Regia Aeronautica, however, suffered from the fact that they were directly under the operational control of the ground commanders and were parcelled out to protect special sectors or to help advance small detachments, instead of being employed in concentrated mass. Goering transferred his main air fleet from the Moscow front early in 1942 to southern Italy and Sicily, the biggest gain being

272 150 Ju-88s. A concentrated attack on Malta allowed Rommel to receive reinforcements, but it cost the axis air forces hundreds of aircraft, especially after a U.S. aircraft carrier ferried in a couple of squadrons of Spitfires.

Rommel's threat to Egypt and the Suez canal was so alarming that in June Gen. Sir Harold Alexander was given over-all command in the middle east; General Bernard Montgomery was put in charge of the 8th army; the U.S. joint chiefs of staff ordered the activation of the U.S. army middle east air force, switching Maj. Gen. Lewis Brereton from New Delhi (10th air force) to Cairo with a single squadron of B-17 four-engine bombers, to form the nucleus of the 9th air force. B-24 Liberators, P-40 fighters and B-25 medium bombers followed soon after, while lendlease Martin Marylands and Douglas Bostons and a few long-range British Halifaxes added to the strength of the R.A.F. middle east. The North African ports were hammered remorselessly, Tobruk and Bengasi becoming so clogged with the hulks of axis ships that they could no longer be used. The aeroplane was beginning to prove itself an "interdictor" of battlefields. Rommel was beaten logistically before he was beaten tactically, with air power playing a decisive part in both aspects. Just before El Alamein (Oct. 1942) Gen. Brereton had a total of 164 aircraft and the R.A.F. 1,117. Opposed to them were about 1,000 German and 1,000 Italian planes of all combat types. The Allied air force set out to destroy them and by Jan. 1943 Rommel had lost 700 planes, many of them captured intact, unable to escape with dry gasoline tanks. The air forces rained destruction on Rommel's forces as he fled to Tripoli. The luftwaffe was beginning to be stretched out thin in a three-front war-western front desense, eastern front and Mediterranean.

In the meantime Anglo-American forces landed in Algeria in Nov. 1942, and the luftwaffe then had to support not only Rommel's Afrika Korps by Jürgen von Arnim's troops in Tunisia as well. By December the German air force in Tunisia amounted to about 150 aircraft, including three Focke-Wulf 190 squadrons from France which could be ill spared from the growing demands on air defense caused by the inauguration of daylight bombing missions by U.S. 8th air force B-17s based in the United Kingdom. Facing the luftwaffe, slightly augmented by a couple of dozen of the latest Italian Macchi 202s, was the newly formed U.S. 12th air force under Brig. Gen. James Doolittle, and a good assortment of R.A.F. Spitfires, Hurricane fighter-bombers, Blenheim IV (Mk. V, Bisley) medium bombers, and the new, fast, allplywood Mosquito reconnaissance plane. A show-down air battle with the luftwaffe in the Mediterranean seemed imminent, with numbers on the side of the Allies, but a slight edge in the quality of the single-engine Me-109G and Focke-Wulf 190 on the side of the Germans. The 190 was a first-class fighter, notable in its use of a BMW 14-cylinder air-cooled radial engine, streamlined cowling and ingenious cooling at all altitudes. The Me-110 was being replaced by the improved Me-210. Ju-87s had a few final flings in early 1943, but Allied fighters were too much for them and they were withdrawn to the Russian front. He-111s, Ju-88s and the improved Dornier 217E made up an effective antishipping bomber force with torpedoes and radio-controlled bombs, operating from bases in northern Italy and the south of France.

Following the Casablanca conference, the occupation of Tripoli, and the bringing up of powerful units of the R.A.F. middle east (designated as the western desert air

forces) and U.S. oth air force, a complete and important reorganization of the entire Allied air effort in the Mediterranean was effected on Feb. 18, 1943. The new organization was on functional air power lines and set the pattern for similar organization in Europe and in India-Burma. Air Chief Marshal Sir Arthur Tedder became Gen. Dwight Eisenhower's air chief, heading the Mediterranean air command, which included the northwest Africa air forces, Malta air force and eastern air command at Cairo. The air tasks to be accomplished were (1) air defense, (2) strategic air attack, (3) battle air attack, (4) air intelligence, including photographic reconnaissance, (5) airfield construction, (6) air supply and maintenance, (7) troop carrier operations and (8) operational training activities in the theatre.

By far the largest section was the northwest Africa air forces commanded by Lt. Gen. Carl Spaatz. For air defense of ports and shipping, a coastal command was set up under Air Vice-Marshal Sir Hugh P. Lloyd. A strategic air force for attacks on axis shipping, ports and air bases in Sicily and Sardinia was set up under Maj. Gen. Doolittle, to whom were assigned B-17 and B-24 day bombers, Halifax and Wellington night bombers, B-25 and B-26 mediums, and P-38 long-range escort fighters. Based on important principles of the use of air power learned in the western desert campaign, Air Marshal Arthur Coningham, Gen. Alexander's tactical air chief who worked in close co-operation with Montgomery's 8th army, was given command of a tactical air force. Its task was to prosecute an offensive air battle for the theatre as a whole in close collaboration with the ground armies, forming an air-ground team with daily, or even hourly joint staff planning and command. This represented a distinctive feature of the campaign, and set a pattern for the final victory in Europe and Asia. Other commands and organizations were formed based on the various air tasks mentioned above.

Coningham's tactical air force used a wide variety of aircraft, including U.S. P-38, P-39 and P-40, and British Spitfire and Hurricane fighters, practically all of them doubling in brass as fighter bombers on occasion. Airacobras (P-39) with their 37-mm. cannon and Hurricane IIds with their 40-mm. Bofors cannon did outstanding work as tank busters. Late in the campaign American Mustangs (P-51A with Allison engines) did notable work as low flying strafers and light bombers, or as swift, far-ranging army scouts, with a dive-bomber version (A-36) coming in just before the invasion of Sicily which was, if anything, even more effective. Tactical air force also had a tactical bomb force and Mitchells, Marauders and Blenheims which could be thrown against axis ground forces in any part of the theatre as the situation demanded. Thus by early spring 1943, the luftwaffe in the Mediterranean was faced with greater numbers and variety of aircraft and superior organization and tactical conceptions. Kesselring drove his units furiously, and desperate air battles ensued, but on the whole it was a losing game, and the German air force was badly mauled. It did a good job evacuating key personnel, including the use of large gliders, but attempts to fly in supplies of oil and gasoline ended disastrously. By May 1, 1943, the position in Tunisia had become untenable for the German air force, and the remaining units retired to Sicily and southern Italy for the vital battles they knew would be coming in the summer. In all North African campaigns the axis lost 5,156 aircraft destroyed in the air and 2,500 destroyed or captured on the ground.

In June Pantelleria was pounded into subjection by a terrific bombing barrage, July saw the invasion and overrunning of Sicily, and landings were made in Salerno in

September. A sudden switching of the entire Allied air strength, including heavy bombers from the Tripoli-based 9th air force, saved the day in a very critical situation. In October, the N.A.A.F. Strategic air force and all heavy bomber units of the 9th were combined in a new strategic air force to be based in Italy for heavy attacks on the axis from the south, the U.S. 15th under Gen. Doolittle. Gen. Brereton and his staff and all 9th tactical air units were secretly transferred to the United Kingdom to build up a new 9th (tactical) air force for the Normandy invasion. The old U.S. 12th air force, under Maj. Gen. James K. Cannon, became a tactical air force co-operating with Gen. Mark Clark's 5th army, while Coningham's T.A.F. and Air Vice-Marshal Harry Broadhurst's desert air force (R.A.F.) co-operated with Montgomery's 8th army. Gen. Alexander commanded all ground forces in Italy, with Tedder still chief of the Mediterranean Allied air forces (M.A.A.F.). By now the luftwaffe and what was left of the Regia Aeronautica were very much on the defensive, although on occasion a very real threat.

By the end of 1943, Gen. Eisenhower had set up his headquarters (later known as S.H.A.E.F.) in the United Kingdom and had taken his entire "first team of the air" with him in preparation for "Operation Overlord." This included Tedder, Spaatz, Doolittle. Brereton and Coningham. Thus, when Gen. Henry Maitland Wilson became commander in chief of the Mediterranean theatre, a new M.A.A.F. top organization was formed. Lt. Gen. Ira Eaker switched from the United Kingdom to become chief of M.A.A.F., which included the strategic air force (U.S. 15th, now under Maj. Gen. Twining, plus British night bombers) and the Mediterranean Allied tactical air force (M.A.T.A.F.), made up of the U.S. 12th (including French units flying B-26 bombers and P-47 fighters) and the R.A.F. desert air force.

From Jan. through Sept. 1944, M.A.T.A.F. flew some 250,000 sorties, dropped 140,000 tons of bombs, destroyed 840 planes, scored 120 "probables" and damaged 520; it lost 900 planes, mostly from German flak. M.A.T.A.F. destroyed or damaged more than 20,000 motor transports, 10,000 railroad cars and 1,200 locomotives. From March to May "Operation Strangle" choked off axis traffic above central Italy by knocking out bridges, blasting rail junctions, etc., and reduced such traffic to a mere trickle which crept along at night. This was followed by "Diadem" from May 11, a close co-operation task with the ground forces which punched through and captured Rome.

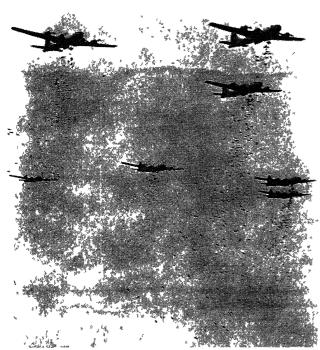

The Mediterranean Allied strategic air force concentrated on long-range bombing by day and night to destroy the axis' ability to produce for war. Targets included aircraft factories, ball-bearing works, power stations, oil refineries, synthetic oil factories, etc. Especially notable was the campaign of the 15th air force against Ploesti, Rumania, which began in April 1944, with 90% of the area's petroleum production knocked out by mid-August. Another feature was the shuttle-bombing between bases in Italy and Russia. Other noteworthy points included the air offensive against the Germans in Greece and the Balkans, aid to the Yugoslavs and the secret formation of the R.A.F. Balkan air force. All this was a distinct aid to the advancing Russian offensive in the south.

Eastern Front.—During the winter of 1941–42 the Russians continued their basic strategy of never allowing the German army or the luftwaffe time for a breathing spell. The 3,000 German aircraft on the eastern front in June 1941 had shrunk to some 1,700 by Feb. 1942, spread thinly along the 2,000-mi. front from Murmansk to the Black sea. This was a hopelessly inadequate force to cover that

first winter's retreats of the German army. Lack of reconnaissance units was a particularly serious handicap. The luftwaffe's outstanding achievement was the supplying of the surrounded 16th German army by air in atrocious weather and often in the face of Russian tank fire, a humble role for the once cocky and offensively spearheading luftwaffe.

By June 1942 the German air force had built up first line strength in the east to about 2,500 aircraft, but with a much lower percentage of reserve aircraft, pilots and crews than the year before. The increasingly formidable R.A.F. night bombing raids on the Ruhr cities, and the growing Anglo-American air strength in the Mediterranean had created critical air fronts which drained off twin-engine and single-engine fighter units from the eastern front. This was especially serious as it was in the fighter category that the soviets had made their greatest gain. The new fighters were designed around V-type liquid-cooled engines by Mikouline (AM-35A, 1,250 h.p.) and Toupolev (M-38, 1,300 h.p.), and included the MIG-3 (I-18, I-61) with inverted gull wings, the YAK-1 (I-26), and the first deliveries of the all-plywood fighter LAGG-3. During 1942 the IL-2 Stormovik, one of the outstanding attack planes of the entire war, began its devastating career against German tanks. Early versions had two 20-mm. cannon and four .55cal. machine guns. The later two-seater versions (IL-4, with pilot and gunner) carried 32-mm. cannon, unusually heavy for wing installation. For dive bombing missions the IL-2 carried four 250-pound rocket bombs or one 1,000pounder. The twin engine YAK-4 and PE-2 were often used on tank-busting or general ground assault missions, as well as high-speed level bombing. The only new German aircraft on the Russian front in 1942 was the improvised anti-tank plane, the Henschel 129 re-engined with French Gnome-Rhone radials of 880 h.p. (which gave trouble) and fitted with a 30-mm. cannon. Another diversion of aircraft from the Russian fighting front itself was the force of 100 to 150 long-range He-111s and Ju-88s manned by highly specialized antishipping crews which carried out devastating attacks against the Anglo-American convoys carrying supplies of aircraft, tanks, equipment and food to Murmansk. A further tipping of the scale in favour of Russian fighter aircraft forces was the increasing flow of Allied models, especially thousands of Bell Airacobras (P-39) and Kingcobras (P-63) of which the Russian pilots were especially fond, P-40s and Hurricanes. It was this fighter edge over the luftwaffe which became an important factor in driving German air force units too far from Stalingrad to help Friedrich von Paulus' 6th army when the Russians launched their counteroffensive after the heroic resistance at that city.

From 1943 to the end of the war, the German air force was compelled to put most of its efforts into the defense of Germany itself, with conservation and improvisation the order of the day. With a few notable exceptions such as in March-April 1943, in supporting the German army counterattack which retook Kharkov, the luftwaffe in the east constantly found itself attempting in vain to stave off the first effects of the repeated attacks of the red army, made at widely scattered points on the long fighting front. The Russians were calling the shots, and on the whole retained the initiative up to the final day of reckoning. There were always at least four separate military fronts to support, with a German air force averaging about 1,700 aircraft. In the southern sector, a small Hungarian air force using obsolescent aircraft and a Rumanian air force

Formation of B-29s releasing incendiary bombs over Japan in June 1945. A huge fleet of these Superforts completed the heaviest raid of the war on Aug. 1, when 6,871 tons of explosives were aimed at strategic targets on the Japanese homeland

of some 200 planes (Me-109, Ju-87, Ju-88) made a useful contribution to a losing cause.

The Germans launched a final supreme offensive effort in July 1943 in the Belgorod sector, the German air force mounting some 3,000 close-support sorties per day. The Ju-87 stuka had a short-lived field day in its attacks against soviet armoured vehicles, guns and troops. The soviet air force, however, strengthened by large accessions of U.S. P-30 fighters (flown via Alaska and Siberia), and a considerable number of Douglas A-20 and North American B-25 attack bombers, were also able to put up 3,000 sorties, with far greater reserves in depth, and the luftwaffe bolt was soon shot. Soviet counterattacks near Orel and near Stalino on the Donets front caused the German air force units to be dispersed again. Thereafter, the only offensive efforts of the luftwaffe in the east were in connection with local German counterattacks to save large sections from being dangerously outflanked.

By the autumn of 1943 Smolensk had fallen, the Germans had withdrawn to the Dnieper and the German air force had been whittled down to about 1,500 aircraft-1,000 from the Black sea to Kiev, 500 from Kiev to the Baltic. More fighter units had been shifted to the west to meet the rising might of U.S. daylight bombing attacks. Bomber units had also been transferred to bolster Kesselring's air forces in the Mediterranean as Italian bomber squadrons dropped out after the capitulation of Italy. Air reconnaissance was so inadequate that the soviet army achieved tactical surprise in practically every attack. Despite the handicaps of being stretched far too thin, of lacking planes and supplies and of being overwhelmed in the air by ever increasing soviet air force superiority, the German air force in the east managed to fight and fly with intensity and determination in an effort to hold off a German ground disaster. In the spring of 1944 the luftwaffe

performed heroically to cover the German withdrawal from the Crimea. June 1944 brought the long-awaited second front in the west, and a few weeks later the soviet army, in a surprise move, began its great offensive in the extreme north, with break-throughs in the central and southern fronts following in due course. The German air force was utterly helpless to stem the tide.

Western Front.—In the air war against Germany, Feb. 1942 was a month of highly critical beginnings. Air Marshal Arthur T. Harris had just become chief of the R.A.F. bomber command, with marching orders to put into effect Sir Charles Portal's "master plan." This plan called for the defeat of Germany by means of the strategic use of air power. Heavy night bombing attacks were to damage or destroy industrial installations in a master list of 60 important war production cities, 40 of which had top priority. This same month saw the arrival in England of Brig. Gen. Ira C. Eaker with a handful of key officers to spearhead the U.S. 8th air force bomber command which was to carry the British plan a step further by attempting to attack in daylight, not industrial cities, but vital parts of key industrial factories, using fast, heavily armed fourengine bombers. It was a scientifically worked out air program of which the number one objective was the destruction of the German air force, to be followed by the destruction or disruption of German war industries. After aircraft and engine factories came oil, synthetic and natural, transportation and communications, ball and roller bearings, chemicals, ordnance, tank and truck factories the blood, arteries and sinews of modern war.

Air Marshal Harris advocated "saturation" raids, concentrated and sustained, to overwhelm the German defense by ever-increasing numbers of aircraft and weight of bombs. The Germans thought they had dropped a lot of bombs when they unloosed 250 tons on Coventry, but the first raid of Harris' regime, March 3-4, 1942, saw 460 tons dropped within 115 minutes against the huge Renault works at Billancourt, near Paris. This rate of four tons per minute was only a start. The majority of the bombers were four-engine Stirlings and Halifaxes, carrying eight and six tons of bombs on relatively short runs. A good example of a special mission was the spectacular 500-mi. daylight raid on April 17, 1942, of 12 new four-engine Lancasters against the factory in Augsburg, Bavaria, which made half the diesel engines for U-boats. By a maximum effort the great Ruhr city of Cologne was blasted on May 30-31 by 1,043 bombers dropping 3,000 tons of bombs in 90 minutes (33 tons per minute), with a similar attack on Essen two nights later, and another on Bremen, June 25-26. These 1,000-plane raids were very much the exception at this period, but they did considerable damage and illustrated what Harris meant by saturation raids. Other principal cities attacked by the R.A.F. included Luebeck, Rostock, Duesseldorf, etc.

In March 1942, the army air forces was constituted as one of the three main divisions of the U.S. army, with Lt. Gen. H. H. Arnold as commanding general. Gen. Arnold was in London during the Cologne and Essen raids, and he promised that the day would come when the U.S. air force would carry out 1,000-bomber missions in daylight against vital German targets. A few weeks later, the existence of the U.S. 8th air force headquarters in the United Kingdom was announced, with Maj. Gen. Carl Spaatz as commanding general and Brig. Gen. Eaker as chief of bomber command, and a total of some 420 combat aircraft. The first U.S. daylight bombing mission was on Aug. 17, 1942, against the railway yards and shops at Rouen in occupied France. German fighter reaction was sharp, but no

B-17s were lost in the first few missions, and the powerful .50-cal. guns in the various turrets and stinger tail brought down several Me-109s and Focke-Wulf 190s on each mission. Up to the end of 1942 the pioneering first wing of the 8th bomber command flew 23 missions against objectives in German-occupied Europe, inflicting substantial damage, shooting down 104 planes, with 108 probably destroyed and 117 damaged. Eighteen Flying Fortresses were lost, 13 by fighters and 5 by flak. However, owing to the diversion of aircraft, personnel, training and maintenance to the newly created 12th air force for the North African campaign, the efforts of the 8th bomber command was reduced to a trickle, and a showdown seemed imminent. At Casablanca, Gen. Eaker completely satisfied the combined chiefs of staff that the U.S. bomber force with its specialty of daylight bombing should be built up, giving half a dozen solid reasons why this would complement the R.A.F. night effort in a highly effective manner. Air Marshal Harris backed him to the hilt, and Operation Pointblank was authorized. This resulted in a directive which was of the highest importance in the European victory, and which ordered a combined "British-U.S. air offensive to accomplish the progressive destruction and dislocation of the German military, industrial and economic system and the undermining of the morale of the German people to the point where their capacity for armed resistance is fatally weakened." It was to be the AAF by day and the R.A.F. by night. Lt. Gen. Frank M. Andrews, pioneer of U.S. air power and commanding general of the G.H.Q. air force from 1935 to 1939, was transferred from his post in Cairo as middle east commander, to England as commanding general of European theatre of operations, U.S. army. The air forces and then the ground forces were to be built up for the coming invasion (Operation Overlord).

According to the revised plan for the combined air offensive the high priority cities for night bomber attack were reduced to 30-6 in western Germany, 16 in central Germany and 8 in eastern Germany, too far away to be attacked frequently. The key rail centre of Hamm was also bombed repeatedly. In the two years from March 1943 when the battle of the Ruhr began, most of the 22 key cities in western and central Germany were blasted over and over again, some of them being finally knocked completely out of the war as military industrial threats. The increase in bomb tonnage dropped during 1943 told the story: 1st quarter, more than 17,000 tons; 2nd quarter, more than 36,000 tons; 3rd quarter, 40,000 tons; 4th quarter (with bad weather), 42,000 tons. In a normal mission overwhelming numbers (400-500) of four-engine Lancasters, Halifaxes and Stirlings (replacing the Wellingtons, Whitleys and Manchesters of the 1940-41 era) dropped 1,000-1,500-ton loads in sustained attacks, sometimes several against one city within a week or ten days. The AAF meanwhile sandwiched in a daylight mission or two, as in the case of Hamburg, in late July 1943.

Concurrent with these saturation attacks were the highly irritating individual attacks, mostly against Berlin, nervecentre of the entire nazi system, by elusive, high-speed Mosquito bombers. With German air defense further thinned out by the growing threat of the U.S. daylight missions, R.A.F. night bomber losses were held below the 4% average. German night fighters were well organized; the Germans' radar warning system, air-borne radar, and the deadly flak were all effective; but the overwhelming numbers, and the fast, concentrated raids were too much for them. By November 1943 the R.A.F. was in a position to carry out a series of concentrated attacks on Berlin.

After Feb. 15, when 2,500 tons of bombs were dropped in 30 minutes (80 tons per minute), it was found that some 326 factories had been destroyed or damaged after November, more than 100 of them of prime importance to the German war effort. It was also estimated that three-quarters of Berlin had been destroyed.

On the daylight side of the combined bomber offensive, the 8th air force mounted its first 100-bomber mission in March 1943. A series of heavily damaging precision attacks, including Vegesack (submarines), Renault (tanks and trucks), and the Focke-Wulf factory at Bremen caused the Germans to build up flak and fighter defenses around the most vulnerable areas and thus definitely weaken the G.A.F. on the Russian front. By late spring new units had arrived, and it became possible to send multiple attacks; B-17 heavies went to one target with powerful P-47 Thunderbolts escorting part way, and B-26 mediums to another target, splitting the German air defensive effort. June and July saw longer range and heavier multiple attacks, with the first daylight penetration of the Ruhr. In late July Brig. Gen. Fred Anderson, chief of the 8th bomber command, loosed his first concentrated attacks on the German single-engine fighter complexes, where Me-109s and Fw-190s were built and assembled.

August 17, first anniversary of the initial daylight mission, was celebrated by sending a huge mission of B-17s and B-24s against the ball-bearing factory at Schweinfurt, and another against the Me-109 factory at Regensburg. Both targets were fiercely defended and losses were about 15%. This was far too high and pointed up the need of fighter escort all the way. The second big attack on Schweinfurt (Oct. 14) saw 60 bombers destroyed out of 320 dispatched (more than 18%), many of them having been shot down by twin-engine fighters armed with air-to-air rockets. From early November, however, the tide turned. P-47s and P-38s with external drop tanks provided fighter escort all the way to the target. Losses dropped sharply to less than 2% per mission; bombing accuracy increased, and 8th bomber command morale soared. A few weeks later, the Merlin-powered Mustang (P-51B, later the D) came into the picture for deepest penetration missions (800 miles and back), soon to be almost universally conceded the outstanding escort fighter of the war.

The leaders of the luftwaffe were frantic. Nearly two years before they had switched to the defensive, with single-engine fighters up 375% from Jan. 1942 to Oct. 1944 and long range bombers off 85% in that same period. The R.A.F. area bombing at night did a lot of damage and drew well-organized night fighter interception, but it was the AAF daylight attacks that made the luftwaffe really come out and fight; this was a prime objective of the Casablanca directive.

From November on, the weather over the continent was so bad that sustained attacks were almost an impossibility. After the summer of 1942 highly trained R.A.F. "path-finder" crews had led the big night bomber formations to their targets by means of a search radar set in the S band, dropping flares as guidance for the others. By Nov. 1943, a few sets of an improved model in the far more precise X band had been developed by the Radiation laboratory at the Massachusetts Institute of Technology, Cambridge, and were operationally tested by the 8th air force. Within a few months this bombing through overcast became an important factor in maintaining a sufficient weight and frequency of attacks to keep up the job which was strategically required.

Jan.-March 1944, saw an all-out effort to destroy the sources of luftwaffe fighter production. The 8th bomber command had about 2,000 B-17s and B-24s in three air divisions, and the 15th bomber command in Italy had 900 bombers (mostly B-24s) in 17 heavy bomb groups. Long range fighter escort was at last available on something like an adequate scale. This was U.S. strategic air force. The R.A.F. bomber command was ready to throw in its entire weight in co-ordinated night attacks. Jan. 11 saw a big attack by 720 bombers on three of the factories. Five weeks later, during a week of reasonably good weather, U.S.S.T.A.F. and the R.A.F. let loose a hurricane of air power against the factories where the Me-109, Fw-190, Ju-88 (now a rocket-carrying day and night fighter), Me-110 and Me-410 were turned out. That week changed the history of the air war. From that time on the luftwaffe rose to battle only when it believed it had local air superiority or when highest priority targets (such as synthetic oil plants) were under attack. The pay-off was the fantastically weak air reaction on D-day, Normandy, 15 weeks later, when the Allied invasion forces provided the most magnificent military target ever offered an enemy air force.

Following blitz week against the aircraft industry, the combined strategic bombing offensive could turn to the main business of destroying Germany's means of continuing the war. The war could not be fought without oil, in huge quantities. The over-all plan for the oil campaign was begun in April 1944, and called for the destruction of 24 synthetic plants and 80 refineries, in six main districts. Three in the Hamburg-Hanover area were assigned to the 8th air force; Silesia, Vienna and Ploesti were assigned to the 15th, with the R.A.F. coming in later for special co-ordinated raids as required. The effect was catastrophic, oil production being cut in half by June with reserves shrinking dangerously. By autumn the luftwaffe, already weakened by the attack on the aircraft factories, was seriously affected by lack of oil and fuel. Training was cut to the bone. It was in this stage that the Me-163 Komet rocket intercepter and the Me-262 Swallow twinjet fighter, using chemicals and diesel fuel respectively, were thrown into battle to the fullest extent possible. Their speed gave them an edge on Allied fighters, but it was a case of too little, too late. If the war had been prolonged another six or eight months, the new jet fighters and highly ingenious rocket powered guided missiles might have robbed the Allies of air supremacy, rendered the big bomber missions militarily uneconomical and jeopardized the entire victory in Europe. The campaign against oil, however, followed by the devastating attacks against transportation in the winter and spring (1944-45) in co-operation with the ground forces actually brought about the coup de grâce. This was according to the explicit testimony of many of Germany's top military leaders. The wehrmacht literally ran out of gas.

Meanwhile, preparations for Operation Overlord were rapidly accelerated early in 1944. On the U.S. side Gen. Brereton's 9th air force was organized as the 9th bomber command, with late model A-20 light bombers and a huge fleet of B-26 mediums, and the 9th, 19th and eventually the 29th tactical air commands, each to team up with one of the U.S. armies being trained for the invasion. The T.A.C.s had a force of P-47s, P-38s and P-51s to be used as fighters and fighter bombers, with photo P-38s (F-5s) for longrange reconnaissance, and some of the P-51s for tactical reconnaissance or scouting. Troop carrier command prepared for airborne operations on a huge scale. New radar

techniques, especially for fighter control, had to be learned, and the use of the new five-in. high velocity aircraft rockets became a part of the last-minute operational training program.

The British counterpart was Air Marshal Coningham's 2nd tactical air force (2nd T.A.F.) for co-operation with the British ground armies. Second T.A.F. and the 9th combined to make up the Allied expeditionary air forces, under Air Marshal Sir Trafford Leigh-Mallory, who thus became Gen. Eisenhower's chief of tactical air operations, under his deputy, Air Chief Marshal Tedder. Second T.A.F. operated with Spitfires, Typhoon fighters and fighter-bombers (including rockets), Mosquitoes and other tactical types.

All through the spring of 1944 as these tactical air forces were being built up they continued the drive begun by the R.A.F. in 1942 to push farther and farther back from the coast the hundreds of large airfields the Germans had constructed throughout France, Belgium and the Netherlands. At the same time a drive was begun to wreck the transportation system so that troops could not be moved in fast enough to oppose the Allied build-up. Low-flying Typhoons, Mustangs and Thunderbolts were especially effective in blowing up locomotives, ammunition trains, etc. In May a concentrated campaign was carried out to cut off Normandy and Brittany by knocking down all the rail bridges across the Seine and the Loire rivers. This new large-scale Operation Strangle, the destruction of airfields, repair bases and of more than 5,000 German aircraft by the tactical air forces alone from January to June, plus the shattering attacks of the AAF and R.A.F. strategic air forces during that same period, cleared the air for the Allied invasion.

To seal off the invasion area the night before D-day, the R.A.F. dropped 5,000 tons of bombs on five important rail yards and on crucial German batteries. German radar stations had been knocked out the day before. At dawn 1,500 U.S. heavies smashed German installations up and down the coast, putting most of the defenders into a daze. More than 1,000 C-47 transports and long trains of gliders had carried some 31,000 airborne troops behind German lines, with the relatively light loss of 26 C-47s and a few of the gliders. The great armada taking Allied troops to the Normandy beaches was covered by the greatest umbrella of aeroplanes ever gathered together. There were more than 4,300 sorties by the 8th air force, 4,800 by the 9th and 2,000 by R.A.F. 2nd T.A.F. Fewer than 50 German planes appeared the first day; more came the second day and each side lost a couple of dozen aircraft. By the end of the third day the Allied air forces had made 27,000 sorties and lost 289 aircraft, mostly to flak. The German air force still had not come out in strength, and it lost only 176 planes—but they lost northern France.

After a stalemate around mid-July, a terrific air barrage on July 25 near St. Lo changed the outlook almost overnight. Hodges' 1st army, under cover of a cloud of Gen. Ellwood R. (Pete) Quesada's 9th T.A.C. fighter bombers, broke through, rolling up the German flank and starting a war of movement. Gen. George Patton's 3rd followed through a few days later, and with its flank protected by Gen. Otto P. Weyland's 19th T.A.C., raced on and reached Paris in two weeks. It was one of the most daring and brilliant campaigns of the war.

By the end of August Gen. William H. Simpson's 9th army was in the field and with it Gen. Richard A. Nugent's 29th T.A.C. The three 9th air force T.A.C.s and the R.A.F. 2nd T.A.F. kept on a continuous raid of destruction, forcing the Germans into the open, or herding them into pockets

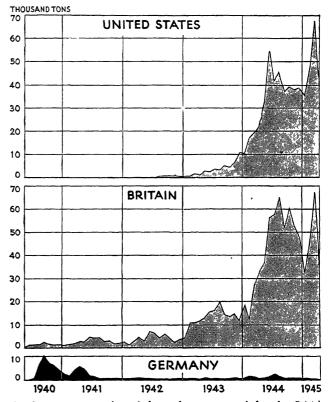

where they were captured by the thousands. In one day (Aug. 18) in the famous Falaise pocket, Coningham's 2nd T.A.F., operating with Montgomery's armies, destroyed-1,159 motor vehicles, damaged 1,724, destroyed 104 tanks and damaged 96. Air-ground co-operation at all levels, joint headquarters, army, corps and division was of the best, with air liaison officers who were themselves pilots and knew what air could and could not do, were attached to each division and called the shots. In the midst of bad weather radar equipment performed miracles, enabling Allied forces to see what was ahead. For greater mobility and for strategic drops behind German lines, British and U.S. airborne forces were organized into the 1st Allied airborne army under Gen. Brereton, a top command with direct access to S.H.A.E.F. for quick orders or confirmation of vital decisions in a rapidly changing situation. With Gen. Eaker's Mediterranean Allied air forces as cover, the U.S. 7th army under Gen. Alexander Patch landed in the south of France in mid-August, and still another T.A.C. was organized, known as the 1st tactical air force (provisional), including U.S. and French units. This new airground team pushed rapidly up the Rhone valley.

The only serious set-back to the Allied advance on all fronts was the counterattack by Karl von Runstedt in the Ardennes on Dec. 16, which called for a quick thrust west and then north to cut off the Allied armies east of Liége, Brussels and Antwerp. Zero-zero flying weather kept Allied air power grounded, and the break-through made considerable headway. On the sixth day the weather broke and the T.A.C.s went into action, smashing towns, rail junctions, bridges, airfields, supply dumps, tanks, vehicles and troop concentrations, dropping 104,000 tons of bombs in 12 days, destroying more than 1,400 German planes (one of the last big reactions of the G.A.F.) and losing about 600, only 50 of these in air combat. By now the luftwaffe was about through. Before the Rhine crossings in March, the AAF knocked out all the jet fighter bases, first in the north and then in the south, and then joined the R.A.F. in the most concentrated smashing of communications in the history of warfare. The wehrmacht was badly cut up, and Russian troops from the east, and Anglo-U.S. troops from west and south completed the victory by early May.

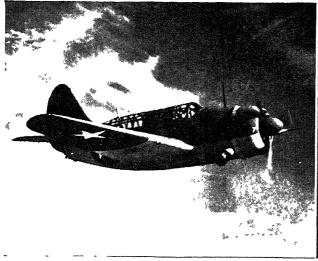

Japan vs. U.S. and Allied Air Forces.-According to Japan's original strategic plan, the Japanese army was given primary responsibility for conquering Malaya, Sumatra and Burma, with air support in northern Luzon. The Japanese navy, following the attack on Pearl Harbor, was to be responsible for operations in the Philippines, Borneo, Celebes, Java, northern New Guinea, the Bismarck archipelago and out to the Gilbert islands and Wake. The air order of battle on Dec. 7, 1941, was as follows: The army had four flying divisions and one flying brigade, totalling 1,375 aircraft, with 550 for the Malayan campaign, 175 for the Philippines, 150 in China, 450 (reserve) in Manchuria and 50 in Japan. The navy had a total of 1,250 aircraft, in four air flotillas (300 for the Philippine campaign, 150 Malayan campaign, 50 for the Marshalls); a carrier force of 6 with 400 planes for Pearl Harbor; 75 seaplanes attached to surface vessels of the combined fleet; and 275 miscellaneous aircraft in Japan.

Facing the Japanese, the United States and its Allies had the following land-based air strength (or weakness?) in the Pacific: U.S. army and navy air forces, 593 aircraft (182 in the Philippines, 12 Wake, 12 Midway, 387 in Hawaii); royal Netherlands Indies air forces, 200 planes; royal air force, 332 aircraft in Malaya; royal Australian air forces, 165 planes in Australia, Solomons, Netherlands Indies and Malaya. Most were of obsolete types.

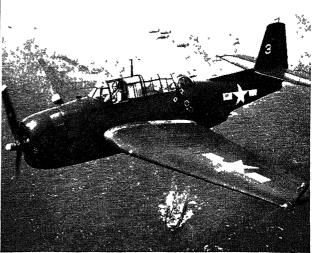

Thus a grand total of 1,290 Allied planes, most of them thousands of miles away from home bases, had to face 2,625 Japanese army and navy planes, more or less on their own home grounds. We have seen the composition of the basic Japanese air team. Following is a brief comparison with the AAF-Navy team, model for model. To meet the agile carrier-based Mitsubishi Zeke 11 (widely known as the Zero), navy and marine pilots had the tough, hardhitting Grumman Wildcat (F4F) for carrier operations and on Guadalcanal, where the Marines also had some P-400s (export version of the early Bell P-39 Airacobra) and AAF pilots had Curtiss P-40s. In Burma-China, to meet the Japanese army fighters, Nakajima Nate and Oscar, the Flying Tigers and China air task force (after July 4, 1942) had rugged Curtiss P-40Bs (4 x .50-cal. guns) and P-40D Warhawks (6 x .50s). The Aichi 99 navy dive bomber Val 11 had an opposite number in the Douglas SBD-3 Dauntless, destined to become the scourge of the Japanese fleet and shipping for the next two years. The Nakajima torpedo bomber Kate 11 was matched by the Douglas TBD Devastator, replaced from the battle of Midway on by the faster, more powerful Grumman TBF Avenger. The Kawanishi four-engine flying boat Mavis 11 was stacked against the stalwart Consolidated PBY Catalina, which with but two engines lacked the range of Mavis. Until the summer of 1942 in China the Japanese army bombers Lily (Kawasaki 99) and Sally (Mitsubishi 97) and navy bomber Nell (Nakajima 96) were the only bombers in the skies, but in July a handful of North American B-25 Mitchells were flown in from India for Gen. Chennault's China air task force, where they put on a performance out of all proportion to their numbers. At no time did the

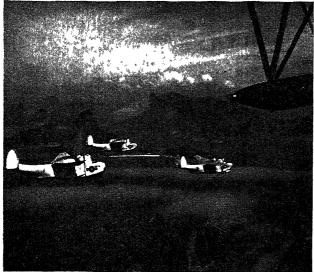

Bombing statistics adapted from charts prepared for the British Chiefs of Staff committee during World War II. Top and centre: Bomb tonnage dropped on axis and occupied territory by U.S.A.A.F. 8th bomber command and the British bomber command respectively. Bottom: Bomb tonnage dropped by the luftwaffe over Great Britain.

Curtiss Helldiver SB2C, navy scout bomber which combined range, speed and armament

TBM Avenger, carrier based navy torpedo bomber

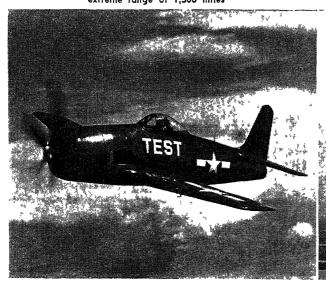

Above: The Martin Mariner, patrol bomber seaplane which guarded navy convoys during World War II

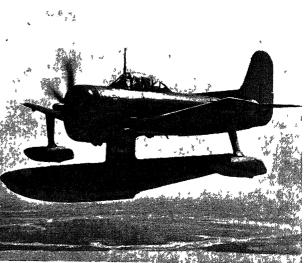

Above: Chance-Vought Corsair F4U-4, U.S. navy fighter plane used by U.S. marines with great effect

Below: Grumman Bearcat F8F, lightweight navy fighter, with a climbing rate of 5,000 f.p.m., top speed of 425 m.p.h., and an extreme range of 1,500 miles

Below: The Seahawk SC-I, high speed float plane, used as a spotter for cruiser and battleship gunfire during U.S. naval operations in World War II

Japanese have a bomber which approached the Boeing B-17E (with stinger tail guns, operational after April 1942) in speed, range, bomb load and defensive fire power, and only toward the end of the war did their medium bombers catch up with the B-25 and the Martin B-26 Marauder (one or two were actually faster and had greater range). On the other hand not until the arrival of the Lockheed P-38 Lightning and Vought F4U Corsair in early 1943 did the Allies have a fighter which could climb and manoeuvre with the Zero (Zeke 11).

Except Nate, which was powered by a nine-cylinder engine of 950 h.p., all of the Japanese aircraft of the 1941-42 period were powered by three principal models of 14cylinder, twin-row, air-cooled radial engines. These were the Mitsubishi Kinsei 40 series, Nakajima Sakae 10 series, and the Mitsubishi Kasei 10 series. The Kinsei and Sakae line ranged from 950 to 1,050 h.p., and were very similar to the Pratt & Whitney R-1830 twin-row Wasp, then rated at 1,150 for take-off, which had been sent to Japan in the late 1930s for production under licence. The Kasei series was more powerful (1,350 to 1,450 h.p.), and compared with the 14-cylinder Wright R-2600 Double Cyclone, rated at 1,600 h.p. Improvement of these engines, and the bringing into production of the compact 18-cylinder 1,800-h.p. Nakajima Homare engine, were important factors in the better performance of later models of the original fighters and bombers, and of the really excellent performance of the new aircraft which were just beginning to make their appearance a few months before the end of the Pacific fighting.

Despite set backs in the all-air sea engagements in the Coral sea and at Midway and Dutch Harbor, the Japanese by July 1942 had established an immense perimeter of conquest in the far east, extending more than half way across the Pacific and westward to the mountain barriers of the India-Burma front. Its swollen empire included a powerful interlocking system of air bases, with literally hundreds of airfields stretching from Formosa to Burma, Malaya, the Netherlands Indies and on through New Guinea to the Solomons. There were powerful air and naval bases in the Gilberts, Marshalls and Carolines. Japan, however, had two fatal weaknesses, its great dependence on shipping, and the vulnerability of its industrial cities to attack by land-based heavy bombers. Thus U.S. strategy was set for a war of attrition against Japanese shipping, along with a thrust straight toward the home islands for heavy bomber bases. At midsummer 1942, however, the main thing was to stop the Japanese advance, and at times it was a desperate business.

During this defensive phase, lasting from Dec. 1941 to about Feb. 1943, the U.S. army air force effort was limited to tactical targets, such as rendering Japanese airfields unserviceable, destroying aeroplanes to dampen the Japanese air offensive, and attacking shipping to disrupt supply and reinforcements. Besides the defensive engagements of the Coral sea, Midway and Dutch Harbor by naval air forces, with substantial assists from the AAF, carrier task forces under Admiral William Halsey conducted hit-andrun raids against Japanese bases in the Central and South Pacific during the first six months of 1942. After Coral sea and Midway the Japanese had but five carriers fit for action, only one of them large. A balance of naval air power in the Pacific, and thus a balance of naval power as a whole, was achieved at Midway, which the Japanese admirals regarded as the turning point of the war.

In late July 1942 Japanese forces landed in New Guinea in an effort to capture Port Moresby. The 5th air force under Maj. Gen. George C. Kenney cut their communica-

tions by air attacks, and by flying in and supplying an entire division of ground troops saved the day, capturing Buna and Gona in Jan. 1943.

In early Aug. 1942 a surprise landing by U.S. marines was made on Guadalcanal, which after bitter land, sea and air fighting was secured by Feb. 1943. The South Pacific theatre commander (from October) was Admiral Halsey, and in Jan. 1943 army air force units, some of which had been in the theatre after Feb. 1942, were organized as the 13th air force under Maj. Gen. Nathan S. Twining, with former Chief of Air Staff Lt. Gen. Millard F. Harmon commanding all army forces in the theatre. From this time on the South Pacific air command was on a quarterly rotating basis, held successively by navy admirals (including Aubrey W. Fitch and John S. McCain), AAF generals (including Twining), and marine generals (including Roy S. Geiger and Louis E. Woods). Although U.S. losses in the Guadalcanal and New Guinea (Papuan) defensive operations had been heavy, the Japanese suffered a crucial strategic defeat. Their advance had been stopped, their strategic plan fatally upset. Most of their best navy pilots who had survived Midway, and some of their best army air units, were lost.

Despite all this, the Japanese retained the advantage of position, and could replace pilots and planes by sending them on relatively short hops over their chain of island bases. U.S. air forces still had the tremendous handicap of distance. Hence the next few months proved to be a fairly evenly matched holding period while the AAF navy-marine air strength was being built up. In the South Pacific new B-17 and B-24 Liberator units added greatly to the sphere of effective bombing and search missions, and B-26 and marine B-25 mediums were also based on the rapidly enlarged facilities on Guadalcanal. Twin-engine Lightnings added greatly to the range, speed and ceiling of AAF fighter capabilities, and the marine-flown Corsair began its career as one of the outstanding land or carrier based navy fighters of the war.

Except for the marine Corsair fighter and Dauntless dive bomber, the above equipment was also characteristic of the 5th air force in New Guinea (headquarters and rear base in Australia), plus the useful Douglas A-20 attack bomber. In both theatres the C-47 (navy R4D) DC-3 type transports did an indispensable job. The Japanese by now also had some improved models and new planes in the air, including the clipped-wing Zero known as Hamp (later Zeke 32), Tony, with an in-line engine, Rufe (Zeke 11 with floats), improved navy bombers Nell 22, Betty 22 and 24, and the flying boat Emily. Their threat, however, was largely based on numbers and availability and not on superiority to U.S. models.

On June 30, 1943, the great double-pronged drive planned in the spring by Admiral Chester Nimitz and Gen. Douglas MacArthur got under way, ending the holding phase and beginning the offensive which a little more than two years later brought the surrender of Japan. This called for: (1) reconquest of the central Solomons to neutralize the great base of Rabaul and clear the decks for the Central Pacific power drive, spearheaded by fast carrier task forces and long-range blows by the 7th air force; (2) an army leapfrogging campaign across the northern New Guinea coast for the springboard to the Philippines, spearheaded by the 5th air force, assisted by the 13th.

The offensive began in May in the North Pacific, army (11th air force) and navy air squadrons co-operating with U.S. landing forces to clear the Japanese from the Aleu-

tians in the world's toughest flying weather. Attu fell on May 30, 1943, catching Kiska in a pincers, and the Japanese forces were driven out, sneaking away in early August. Attu was converted into a heavy bomber base, and from then on army Liberators and Mitchells and navy Venturas, aided by the Loran electronic navigation system, carried out search and strike missions against Paramushiru and other bases in the Kuriles.

In the South Pacific the offensive started up the ladder of the central Solomons, capturing the big airfield of Munda, New Georgia, on Aug. 7, 1943, which the seabees soon turned into a huge air base for the 13th air force, marine and navy air units. Other Japanese island bases in the Solomons were captured during the next few weeks, while ceaseless attacks were made against Rabaul. In November, landings were made on Bougainville, and big airfields for further advances were ready by the end of the year. The capture of Green island in Feb. 1944 completed the Solomons campaign.

In the re-conquest of New Guinea (S.W. Pacific theatre), Gen. Kenney's 5th air force accepted major responsibility for the three main aspects of tactical air power, later defined as gaining air superiority (phase one, operations), isolating the battlefield (phase two) and working in close co-operation with advancing ground forces (phase three). The battle of the Bismarck sea (March 3-5, 1943) was a classic example of phase two, in which a large convoy and several score Japanese planes were destroyed in a spectacular demonstration of minimum altitude bombing.

After destroying 309 Japanese planes at the big air base at Wewak in four days, largely by the effective use of low-flying planes dropping parachute bombs (parafrags), the New Guinea leapfrogging operation began in September 1943 with the capture of Salamaua, Lae and Finschafen, with brilliant tactics in the use of aviation engineers and air supply.

In March 1944 a force of B-24s with long-range fighter escort (P-38s and Republic P-47s with drop tanks) smashed 219 planes at Hollandia. In April Hollandia was taken in a long jump, by-passing Wewak, Admiral Marc A. Mitscher's task force 58 and the 13th air force (advanced units now based on Manus in the Admiralties) co-operated. Wakde and Biak islands fell in May, Noemfor and Cape Sansapor at the tip of New Guinea in July. Morotai in the Halmaheras was assaulted on Sept. 15, with landings in the Palaus on the same day. The next stop was the Philippines.

By Sept. 1943 the navy was ready in the Central Pacific. Admiral Mitscher's famous task force 58 (so designated as the 8th task force in Admiral Raymond A. Spruance's 5th fleet) began its free-ranging and practically irresistible campaign with a big raid on Marcus island, followed by others every few days on various Japanese strong points in the Gilberts, Marshalls, northern Solomons and Rabaul, the latter just preceding a tremendous air attack by Gen. Howard K. Ramey's 5th bomber command in New Guinea. The carriers of task force 58 were of the 27,000ton Essex class, carrying 80 to 90 aeroplanes-new Grumman Hellcat (F6F) fighters, Curtiss Helldiver (SB2C) scout bombers and Grumman Avenger (TBF) torpedo bombers, a powerful triple-threat team. The fast carrier task force included battleships, cruisers and destroyers in proportion, but the carrier was queen. There was also a new supplytrain setup which enabled the task force to stay more than 2,000 mi. away from its main operating base for weeks at a time.

In November the other member of the Central Pacific power-team, Maj. Gen. Willis Hale's 7th air force (which in April had taken a 2,000-mi. leap from Hickam field, Oahu, Hawaii, to Canton in the Phoenix islands and later to Funafuti) took a 1,000-mi. step toward Tokyo by moving into the recently captured Tarawa and Makin. From these bases in the Gilberts they joined task force 58 in hammering key Japanese bases in the Marshalls in preparation for the surprise capture of Kwajalein in late Jan. 1944, and Eniwetok a few weeks later. The fast-moving 7th air force soon moved into these bases in the Marshalls, while task force 58 went on to attack Truk and other Caroline bases. June and July saw the biggest amphibious operation to that date in the capture of Saipan in the Marianas, followed by Guam and Tinian, during which T.F. 58 had its greatest kill of Japanese planes in the chase known as the first battle of the Philippine sea. Capture of the Marianas bases, soon to be occupied by AAF 21st bomber command (B-29s), spelled the beginning of the end for Japanese imperial ambitions.

During operations around the Philippines in Sept. and Oct. 1944 carrier forces of Halsey's 3rd fleet dominated the air action. Mitscher's task force 38 (bigger and more powerful than his ubiquitous T.F. 58) had some 1,080 planes, and T.F. 77, with smaller carriers, had 600. Gen. Kenney's far eastern air forces (5th and 13th) had 1,460 planes with 525 in ready reserve, while the 7th in the Marianas, Palaus and Marshalls had 525 more. The important point at this stage was that the mobility of the carriers permitted massing of air power at a particular time and place. The Japanese navy and air forces missed a great opportunity shortly after the invasion of Leyte, but U.S. naval surface and air forces administered a decisive defeat. From a toehold on Tacloban air strip (Leyte), 5th fighter command plus a force of B-25s sank convoy after convoy. Landings on Mindoro in December permitted the 5th air force to bring up its main bomber strength, releasing the carriers for other duties, and this was the beginning of the end of the Philippines campaign. They not only destroyed 2,000 Japanese planes, but rendered all airfields and repair facilities completely unserviceable.

From Luzon in January B-24s, B-25s, P-38s and P-51s put on an intensified campaign against shipping, the biggest Operation Strangle in history. They also began neutralizing Formosa for the Okinawa campaign. The 13th (the jungle air force, based on Morotai after Sept. 1944) took care of all points south and continued important strikes (with the 5th) against the oil centre of Balikpapan, coming up into the Philippines when units of the 5th went on to Okinawa. In the Central Pacific the final arch in the bridge was put in place with the capture of Iwo Jima in late Feb. 1945. This converted what had been a warning station and interception point against the increasingly heavy B-29 attacks from the Marianas into an emergency base and refuelling centre for returning B-29s in distress. Iwo Jima also became a forward base for 7th fighter command P-51D and later long-range P-47N fighter sweeps over Japan, also carried out effectively by navy and marine carrier fighter units. Iwo saw the first large-scale use of the radar GCA (ground controlled approach) talk-down system, in which scores of B-29s, P-61 Black Widows and marine F7F night fighters and other types were landed in all sorts of weather. In May the 7th air force moved from the Marianas to Okinawa, becoming part of far eastern air forces, under Gen. Kenney, who was shortly afterward named tactical air force commander for the entire theatre, with Gen. Spaatz as the strategic air force commander.

Radio-controlled U.S. navy plane being directed by the pilot in its mother plane. He took over after the plane reached the air by remote ground control

The Japanese had lost an entire air force in the Solomons and New Guinea between mid-1942 and mid-1944, and another one in the Philippines. Aggregate losses during the course of the war were something like 50,000 planes, of which 20,000 (40%) were combat losses; the rest were training, ferrying and other noncombat losses. A Tokyo diet report revealed that aircraft production during the first nine months of the war averaged between 600 and 700 per month; about 1,400 per month during 1943; 2,300 per month in 1944; with a peak of 2,857 in June 1944. After an earthquake in the Takai area and the low-level mass incendiary B-29 missions in March 1945, production began falling off sharply, dropping to 1,003 in July. During 1943 and 1944 technical improvements were increasingly apparent, especially in engines, armament and general ruggedness of aircraft. The new types began to be encountered in limited numbers during and after the critical campaigns to seize the Marianas, Philippines and islands in the inner empire, but even then the bulk of the 1,500 to 2,000 planes per month destroyed by U.S. air forces were simply improved versions of the standard models. Most important of the group using souped-up versions of the 14-cylinder engines were Jack 11 (Raiden or Thunderbolt), first Japanese 400-m.p.h. fighter, Judy (Susei or

Comet) scout bomber, Jill torpedo bomber, Dinah 3, fast long-range reconnaissance plane, and Irving (Gekko or Moonbeam) night fighter. The latest models of all were powered by the powerful, compact 18-cylinder Nakajima Homare engine of 1,800 h.p., 2,000 h.p. with water-methanol injection. In the 400–425 m.p.h. class were the navy fighters George, Sam and Luke and the army fighter Frank; Frances (Ginka or Milky Way) and Grace were among the fastest bombers in the world (350 m.p.h.).

After the overwhelming defeat of the Japanese air forces in the Philippines, however, there was only one recourse left—a Kamikaze (Divine Wind) or suicide air force, for which preparations had been begun after the defeat in New Guinea. This capitalized on the only asset the Japanese still possessed, the willingness of their pilots to meet certain death. In the Philippines the suicide tactics were on an individual scale, but in the Okinawa campaign the mass Kamikaze attacks posed a highly critical threat, 42 U.S. ships being sunk and 216 damaged. In all some 2,550 suicide missions were flown, including those in Baka, the Kamikaze glider-bomb, 475 or 18.6% being effective. The Japanese air forces, at the time of the surrender, included 5,000 tactical planes, plus 5,400 Kamikaze planes.

The Allied strategic plan contemplated that the actual defeat of Japan would be accomplished by operations in the Pacific, but in the meantime it was essential to defend

India and to assist China. The main contribution was air and logistic support. Probably more than any other, China-Burma-India was an air theatre. The royal air force and U.S. 10th air force in India and the 14th in China had a great variety of duties. The Allied air achievements in Burma made it possible for Allied troops to exist in the jungle by supplying, evacuating and transporting them on an unprecedented scale, and by making the Japanese position untenable, through starvation and destruction of supply bases. The latter disappeared in a welter of bombed bridges, river boats, railroad trackage and freight junctions. In China it achieved command of the skies over Chinese troops, provided much of the fire power even in ground operations, and tore gaping holes in the Japanese supply routes on land and sea. Between India and China it flew the Hump of the 14,000 to 18,000-foot passes through the southern Himalayas in the greatest sustained transportation achievement of the war. Despite atrocious weather and highly dangerous flying conditions, far more military cargo was transported over the "aerial Burma road" than had been carried over the tortuous road itself, with the India-China wing of the air transport command attaining a peak of 71,000 tons in June 1945.

The R.A.F. in India was under the command of Air Chief Marshal Sir Richard Peirse, who became air commander for the theatre under Admiral Lord Louis Mountbatten when the southeast Asia command was organized at the end of 1943. Air operations were under Maj. Gen. George E. Stratemeyer, commanding general of the eastern air command, made up of a strategic air force (U.S. 10th and R.A.F. units) and tactical air force (R.A.F. and AAF units), plus a photo wing, troop carrier wing and Col. Philip Cochran's air commandos. The 10th had been commanded by Generals Lewis Brereton, Clayton Bissell and Howard C. Davidson. Equipment in India-Burma included R.A.F. Hurricane fighter bombers, Blenheim mediums, lend-lease Vengeance dive bombers, AAF P-40s, B-25s, B-24s, and A-36s (dive bomber, rocket-firing P-51s).

In China Gen. Claire Chennault had successive command of the American volunteer group, China air task force and from March 1943 the U.S. 14th air force, to which was attached U.S.-trained Chinese pilots flying P-40s and B-25s in the Chinese-American composite wing. The 14th made up for its tiny size and constant logistic limitations by masterly tactics, strategy and deception. Up to May 19, 1943, when a group of B-24s arrived, the only equipment was a handful of P-40s and B-25s. From the autumn of 1943 a few of the B-24s equipped with LAB radar (low altitude bombing device) were highly successful in sinking Japanese shipping in the south China sea. More than 2,350 Japanese aircraft were destroyed in China, including the army fighters Oscar, and later Tojo, which were almost wholly confined to this theatre. By early 1943 the Allied air forces had aerial superiority in the entire China-Burma-India theatre, and they never lost it.

During all this time the most destructive form of warfare ever waged on land, sea or in the air was being prepared—VLR (very long range) air power in the form of the Boeing B-29 Superfortress and the 20th (global) air force. Designed in 1940, flight-tested over Seattle, Wash., by Boeing's chief test pilot Eddie Allen in Sept. 1942, the XB-29 was the biggest, fastest, most complex aeroplane ever conceived up to that time. It had a 141 ft. span, was 99 ft. long, was able to fly a 16-hr. mission, was powered by four Wright 2,200-h.p. engines, had a 20,000-lb. bomb capacity, 135,000-lb. maximum overload in bombs and gasoline, a speed of 350 m.p.h. and a range of 3,000 mi. It had central station fire control in remote turrets, and an amazing array of radar and electronic equipment.

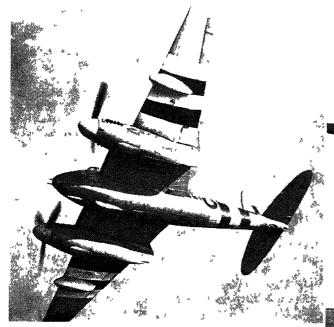

Besides Boeing (three plants), Bell (Marietta, O.) and Martin (Omaha, Neb.) were brought into the production picture, with many hundreds of subcontractors. The 2nd air force, Colorado Springs, Colo. took over the complex training program, starting with the 58th wing V.H B. (very heavy bombardment) of the 20th bomber command. The 20th air force was at H.Q. AAF, Washington, under the jurisdiction of the joint chiefs of staff, with Gen. Henry H Arnold as their executive and Brig. Gen. Hayward S. Hansell as his deputy and commanding general of the 20th.

The Marianas had been selected as the operational base best adapted to knock Japan quickly out of the war, but the B-29 was ready before the big bases on Guam, Saipan and Tinian could be prepared. Hence the 58th wing (20th bomber command, under Brig. Gen. K. B. Wolfe) went to India in April 1944, and set up forward bases in the Chengtu area, China, for refuelling and take-off for bombing key targets in Japan, Manchuria, Formosa, etc. The first mission was on June 15, 1944; 75 B-29s attacked the steel works at Yawata (Kyushu), 47 reaching the target. Fifteen missions were run between then and Nov. 21. In September Maj. Gen. Curtis E. LeMay was switched to the 20th bomber command after a brilliant record with the 8th air force (United Kingdom).

By mid-Sept. 1944, Gen. Hansell, now commanding general of the 21st bomber command, arrived in the Marianas in a B-29, followed by the 73rd wing V.H.B. On Nov. 24 the first mission against Japan was run, with 80 B-29s led by Brig. Gen. Emmett O'Donnell flying 1,500 mi. along a line of Japanese-held islands to smash the Musashima aircraft factory, Tokyo. Despite treacherous weather with terrific winds, Japanese fighters and anti-aircraft opposition, 15 missions were run up to Jan. 26. On that date Gen. LeMay moved from the 20th bomber command in India to take command of the 21st on Guam, Gen. Hansell returning to the U.S. to train additional V H.B. wings, including the 315th equipped with the super-precision Eagle radar bombsight. Brig. Gen. Lauris Norstad was now commanding general of the 20th air force in Washington.

Brig. Gen. Roger Ramey took over B-29 operations in the China-Burma-India theatre, and between Nov. 1944 and April 1945 carried out some 30 bombing attacks on widely scattered strategic targets, including Rangoon, Bangkok, Formosa, Singapore, etc. In April the planes and crews of the 20th bomber command moved to new airfields on Tinian, adding its strength and experience to the 21st. In July these units switched to Okinawa to form the nucleus of the transplanted 8th air force, under Lt. Gen. Jimmy Doolittle, which however, owing to the sudden ending of hostilities, never saw combat action.

During Feb. 1945 Gen. LeMay increased his striking force from 100 to 200 Superforts, dropping 600 tons of bombs. Losses were still fairly high and bombing results not too good. In March he made a courageous decision which speeded the defeat of Japan, although it appeared to run counter to established U.S. strategic bombardment doctrine. This was to send larger formations, on night missions, armed with incendiaries, at 5,000 to 8,000 ft., permitting less gasoline and more bombs, without armament, without fighter escort, relying on darkness and speed for safety and radar for navigation and general bombing accuracy, with entire cities as targets. It worked. Tokyo, Osaka, Kobe, Nagoya, with their thousands of home industrial setups as well as large factories were fire-blitzed

Upper right: The Mosquito Mark XVI, British light night bomber designed to operate at altitudes of better than 30,000 ft. The plane was also used for photographic reconnaissance

Right: The Lancaster III, used by the R.A.F. bomber command for the major part of its tonnage dropped during World War II

Below: The Hawker Hurricane II, British fighter plane which functioned as a major weapon of the R.A.F. during operations over France early in 1940 and in the battle of Britain

Lower right: The Supermarine Spitfire XIV, British interceptor plane with a maximum speed of 448 m.p.h.

within ten days, and 32 square miles of Japan's four most important cities were burned out.

During the next five months nearly a score of cities received increasingly heavy blows as new V.H.B. wings joined the newly organized U.S.A.S.T.A.F. (U.S. army strategic air forces in the Pacific) under Gen. Carl Spaatz, including the 20th in the Marianas, now under Gen. Twining, and the 8th on Okinawa, LeMay becoming Spaatz' chief of staff. Losses of B-29s became extremely light as raids increased to 600-plane missions in July. Superfort tonnage rose from about 13,500 tons in March to more than 42,500 tons in July, with more than 25,000 tons on 14 cities during the first two weeks of August. Then on Aug. 6 and 9, in single-plane missions, atomic bombs were dropped on Hiroshima and Nagasaki, hastening a surrender which, wholly apart from the atomic bombs, would have become necessary very shortly as complete collapse was imminent, according to the testimony of Japan's top military and naval leaders. Thus, without invasion, by a tight blockade by sea and air power, and the destruction of more than 60 Japanese cities in five months by very long range air power, the victory was won.

Planes that Missed the War.-When Allied technical intelligence teams arrived in Germany in the late spring of 1945, they found such a wealth of technical information that the records ran well into the hundreds of tons. Much of this information was the result of heavy German investment in aeronautical research during the mid-30s, including rockets, jet propulsion and supersonic speed wind tunnels. Several hundred projects in various stages of development were found (including 138 various types of guided missiles), some of which were practically ready for large scale production in underground factories. Conventionally powered aircraft included the Blohm & Voss Bv-155B high altitude fighter, Focke-Wulf Ta-152 day and night fighter, the Dornier Do-335 front and rear propelled fighter and the Ju-388 high altitude day fighter, night fighter, fast bomber and reconnaissance plane. Jet fighters included the 590-m.p.h. EF-128, Focke Wulf 183 and others, while jet bombers appeared in great variety, including the Ju-287 with two, four and six units and sweptforward wings, the Arado 234 with two or four units and the Horten flying wing. Blohm & Voss and Focke-Wulf had composite-engine bombers, each powered by two Daimler-Benz inverted-V piston engines and two Heinkel-Hirth O11 turbojets. Rocket planes included the Me-263 (163 saw service) and Me-328, and rocket-powered guided missiles were far too numerous to mention, Bp-20 Natter (Viper) with its climb to 37,000 ft. being particularly deadly.

Britain's crop of bombers and fighters just on the edge of operational service at V-J day was impressive. Big four-engine bombers included the Avro Lincoln and Vickers-Armstrong Windsor, successors of the Lancaster and Wellington. The Bristol Brigand was a twin-engine multipurpose fighter-bomber (successor of the versatile Beaufighter), and the Fairey Spearfish and Blackburn Firebrand were new naval dive-torpedo bombers. Jet fighters included the De Havilland Vampire, with Goblin turbojet, fast and easy to fly. Piston engine fighters in the 450–480 m.p.h. class included the Spitfire 24 and related Spiteful, Seafire and Seafang, De Havilland Hornet and Hawker Fury (485 m.p.h. with methanol-water injection).

The U.S. army air force's 490-m.p.h. lightweight Mustang, P-51H, was in the theatre but was not used operationally, which was also true of U.S. navy Ryan FR-1

Fireball jet-cum-propeller carrier fighter. A P-80 jet fighter unit was about to go. The P-82 Twin Mustang long range fighter and Northrop F-15 photo reconnaissance plane were both almost ready for action. Important navy models which had flown but were not operational included Goodyear F2G Corsair with Wasp Major engine, Lockheed P2V Neptune (of which the record-breaking "Truculent Turtle" was the most famous at the end of the decade), McDonnell XFD-1 Phantom jet fighter, Martin BTM Mauler, Douglas AD-1 Skyraider and Curtiss BT2C dive and torpedo bombers. The army air force's 1946 crop included Convair's propjet-turbojet powered XP-81, twin-jet bomber Douglas XB-43, Republic XP-84 Thunderjet, Northrop XB-35 flying wing and Convair six-engine XB-36.

The U.S.S.R. had a couple of advanced YAK fighters ready for action, and after the end of the war British sources reported one or two jet fighters in the 600-m.p.h. class, powered by jet units well advanced in Germany at the end of the European fighting and completed by German technicians in the Russian zone. A U.S. source reported a Russian jet fighter with two units, one on each side of the fuselage, as in the Bell P-59.

Postwar Trends.—Results achieved by Allied air power in the war in Europe and in the Pacific, together with signposts as guidance to the future were found in the conclusions of the reports of the United States Strategic Bombing survey, a distinguished group of 300 civilians, 350 officers and 500 enlisted men activated in Nov. 1944 by the secretary of war:

Allied air power was decisive in the war in western Europe . . . In the air its victory was complete; at sea, its contribution, combined with naval power, brought an end to the enemy's greatest naval threat—the U-boat; on land, it helped turn the tide overwhelmingly in favor of Allied ground forces. Its power and superiority made possible the success of the invasion. It brought the economy which sustained the enemy's armed forces to virtual collapse . . . It brought home to the German people the full impact of modern war with all its horror and suffering. . . .

The experience of the Pacific war supports the findings of the Survey in Europe that heavy, sustained and accurate attack against carefully selected targets is required to produce decisive results when attacking an enemy's sustaining resources. It further supports the findings in Germany that no nation can long survive the free exploitation of air weapons over its homeland . . . Science has increased tremendously the destructive capability of modern weapons and promises further developments in the future. It is not generally realized the degree to which basic scientific research was neglected in the United States during the course of the war in order to concentrate on the belated development of the specific weapons immediately required, nor the degree to which we lagged behind Germany in advanced aerodynamics, jet propulsion and the development of guided missiles. In air armament and torpedoes, even the Japanese were ahead of us . . . This type of work has become so complex that expenditures for research and development in the order of 1,000,000,000 dollars annually may be required to assure an acceptable degree of national security. .

Within a department of common defense which provides unity of command and is itself oriented toward air and new weapons, the Survey believes that in addition to the Army and the Navy, there should be an equal and coordinate position for a third establishment. To this establishment should be given primary responsibility for passive and active defense against long range attack on our cities, industries and other sustaining resources; for strategic attack, whether by airplane or guided missile; and for all air units other than carrier air and such land-based air units as can be more effective as component parts of the Army or Navy.

Under the over-all direction of the AAF Scientific Advisory board, composed of outstanding scientists, the U.S. army air forces undertook a comprehensive program in cooperation with government and university research organizations and scientific and engineering groups of the aircraft industry, including the following fields: (1) super-

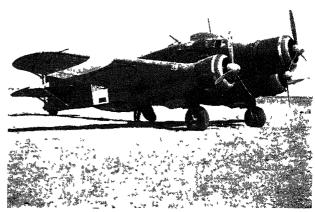

sonic aircraft, piloted (such as the Bell XS-1) and pilotless (such as Boeing GAPA—ground to air pilotless aircraft); and winged missiles having velocities approaching the meteoric; (2) nuclear energy applications for propulsion of aircraft and missiles; (3) flight and survival equipment for use above the atmosphere, including space vehicles and devices for use therein; (4) aircraft and missile operating technique development. Under the technical guidance of the Applied Physics laboratory, Johns Hopkins university, Baltimore, Md., the U.S. navy adopted a similar program, possibly of even broader scope. By autumn of 1946 the National Advisory Committee for Aeronautics had no less than 11 wind tunnels engaged in research in supersonic speeds for piloted and pilotless aircraft and guided missiles.

Similar developments were under way in Great Britain, where a £20,000,000 National Aeronautical establishment was planned, with the proposed National Gas Turbine establishment and the National Aeronautical college close by. Great emphasis was being laid on jet propulsion, rockets and guided missiles, in addition to a new program of rocket research stations and testing ranges in Australia. The U.S.S.R. reported that nuclear energy, radio location and jet propulsion were among the major problems for soviet scientists.

Such developments indicated clearly that the piloted aeroplane as a striking weapon was on the way out, but it was also certain that the new superweapons were still years away as far as operational use was concerned. Military and naval planning staffs were thus having to work with material available. The U.S. army and navy air forces were rapidly going over to jet-powered fighters, as were the British, with Canada, Australia, Sweden and Switzerland (among others) equipping their air forces with British jet aircraft and turbo-jet engines. The soviets were undergoing a similar transition. Jet bombers were also well on the way. The Military committee of the United Nations was working constantly toward the goal of a readily available, powerful international air striking force for the prevention of wars. (N. F. S.)

Strategic Role of the U.S. A.A.F.—Japan, after watching Germany's rapid movements in the early years of World War II, came to the conclusion that its naval aviation could deliver a death blow to the U.S. navy anchored in Pearl Harbor. Then, without opposition in the Pacific, a line of outposts could be established that would prevent any attacks being made on Japan proper. The Japanese armed forces would be supreme in the Pacific. Those outposts would be so remote that attacks on the homeland would be impossible, either by air or by surface forces. Under those circumstances a compromise peace would be the worst condition that Japan would have to meet.

Air power certainly lived up to the expectations of the Japanese leaders, as a striking force, when it destroyed the U.S. fleet in Pearl Harbor; but the Japanese strategists guessed wrong in so far as the balance of the plan was concerned. They could not conceive of the United States building up an army, navy and an air force as rapidly as it did. Almost before the smoke had cleared away from the debris in Pearl Harbor, the co-ordinated advance of the army, navy and air force started across the Pacific. As the Japanese were pressed back, its fleet and its air force were destroyed, bases were secured for operations of the U.S. army air force, and attacks were made on the Japanese homeland. These aerial attacks destroyed Japanese industrial and transportation facilities; made it impossible for critical materials to be received in Japanese ports; undermined Japanese morale, destroyed its will to fight and

Savoia-Marchetti S-79, Italian torpedo bomber, parked at a .U.S. air base in Sicily

brought about the end of the war. The war ended with some 4,000,000 well-trained, well-equipped, undefeated Japanese soldiers waiting for U.S. troops to make a landing. Such were the paths that the power of the air outlined for world events to follow; such was the place in history that aviation carved for itself during World War II.

One of the cardinal principles as taught by the U.S. army air force for many years was: "Strategic bombing, properly carried out, can destroy the sinews of war; can wreck transportation systems; can prevent the flow of materials and personnel to operating armed forces; can deprive the fighting forces of the wherewithal with which to continue battle, and thus can bring an end to the war." That principle was not accepted by the German leaders, who, by 1942, were convinced that fighting planes and ground defenses could make daylight bombing so expensive in planes and trained crews, that bombing to complete destruction was impossible. In this, Germany was supported by many British leaders. They had Germany's attacks on English targets, and the R.A.F. attacks on German targets -neither operation a success for daylight bombing-as criteria for their position. Neither the Germans nor the British, however, took into consideration the great initiative of the U.S. airmen, the rugged U.S. air equipment and the technique of operations of the U.S. army air force.

The U.S. certainly found the going tough on its daylight raids; but it kept on going, in spite of losses. The German opposition became less and less. U.S. army air force units were soon able to make shuttle bombing runs, taking off from England or Italy, flying all the way across Germany and landing in the U.S.S.R. The U.S. airmen met the German air force on its home grounds, they destroyed industry after industry, demolished railroads and depots, canals and warehouses, and soon made the German air force impotent. The heart was taken from the German fighting machine, and it soon collapsed. This, however, did not happen until the German scientists had brought out many new devices, gadgets and weapons, such as the V-1, a pilotless plane, and the V-2, the rocket that caused much consternation among Allied personnel. Actually, these new devices were far more of an irritation than a danger; but had the Germans been allowed to develop them into articles of production, they might well have caused considerable confusion among the Allied commanders. They did give definite indications as to the weapons of the future, however.

Prior to 1940 the U.S. army air force was practically a paper organization. It had few planes, no industry to

speak of when quantity production was desired and a limited number of pilots. Its operating technique had never been tested. When Pres. Roosevelt approved a program in 1939 pointing toward the defeat of Germany and Japan through the air, all phases of air power for the United States were given a definite start. The principle was then accepted for the first time that mere aeroplanes, no matter what the numbers, could never make an air force, nor give a nation air power. For any nation to have an air force there must be an air industry, a flexible training system, that could be expanded rapidly, for pilots and for all other personnel, depots for supplies and for reserve personnel, air bases from which the planes could operate, radio, navigational, weather and other equipment to give service to the planes over the airways and at the bases.

The war clouds in Europe at the start of World War II gave the U.S. air industry a very healthy growth because of the planes ordered. At that time the U.S. aeroplane strength in the army air force was about 1,800 combat planes. The first real push toward air power came with the fall of Paris. Congress then changed its ideas from: "Whom are you going to fight?" to: "What do you need?"; "How much money do you need?"; and, "What is holding you back?" Funds were no longer a bottleneck. The aircraft industry built up rapidly from a total of about 3,000 planes a year in 1939, until a production of about 7,000 a month was reached in 1944. Pilot production paralleled plane production: 700 a year in 1938, to 103,000 a year in 1944.

The U.S. army air force very fortunately had some tried and true planes when Japan struck in Dec. 1941. These planes coming off production lines in fairly large numbers, made it possible for MacArthur to hold back the Japanese air force when his back was against the wall in New Guinea. These old planes flew from a carrier to the bulge of Africa and then across the jungles and deserts of central Africa, to take their places alongside the R.A.F. in Egypt, where they played a magnificent part in driving Rommel back to Tunisia. They were used to train some 500,000 crew members who fought in the air in all parts of the world.

These prewar models—the P-38s, 39s and 40s, the B-25s, 26s, the A-20s, the B-17s and 24s and the C-46s and 47s—all did well until they were superseded by later models. They were re-equipped, remodeled and redesigned, but they held the line in the air until the P-47s and 51s, the A-26s, the B-29s and the C-54s came along to take their places (see above). U.S. designers did not stop their drawing board work. New types of planes were constantly being tested: the latest models never stopped coming out of the engineering sheds at plants all during the war. Had the war lasted another year, U.S. jet planes, P-59 and P-80, the large bombers, B-35 and B-36, the most modern and best performing yet produced, would have been in combat.

In the early days of World War II, with German submarines picketing the sea lanes of the Atlantic, and the Japanese holding islands all over the Pacific, air transport service became most important. Vital supplies and critical items, as well as important people, had to reach their destinations in the shortest possible time. The U.S. army air transport command carried almost anything, anywhere in the world—over the Pacific and the Atlantic; in Europe, in Asia and in Africa; for the island fighting leading up to Japan itself. The air transport service proved itself a necessity to the land, sea and air forces. These world-

wide operations of the transport command, and the ferrying of combat planes to their bases in the combat zones, gave invaluable experience for peacetime commercial flying.

The problem of supplying the Chinese to keep them alive as an active combatant nation was one of the most important operations. China was cut off from its Allies by a Japanese-occupied coast line, by a neutral Russia and by that almost impassable barrier, the southern spur of the Himalaya mountains. Crossing northern Burma by road was impossible, as the Japanese had possession of the critical points along the road. These facts, coupled with the difficult weather for flying across Burma, and the exceedingly rough terrain, gave the Japanese confidence that air transportation of supplies into China was not practical. With such a challenge, it was not long before the air transport command started flying across the Hump. As the personnel attained more experience, and the number of planes increased, the tonnage carried built up, and China was kept in the war. The going was rugged when the run started, and the tonnage taken into China rarely exceeded 2,000 tons a month. Then it rose to 4,000 and 8,000; and the Chinese armies took on new hope. Months passed, and the tonnage increased to 16,000; to 20,000 and the Chinese armies started fighting back at the Japanese. By July 1945 the monthly tonnage had reached a figure of 70,000 tons-a tonnage about four times the maximum amount ever taken over the Burma road, and there were no more fears of China's being forced, by lack of supplies, to make a separate peace.

During the decade 1937–46, the air forces of the world changed war-making, created new techniques for destroying enemy vital points and outlined new paths for the future, for peace or war. Military flying across oceans took the mystery out of transoceanic navigation, proved that flights across the North Atlantic need be no more dangerous in winter than in summer, established bases, communications systems, around the world and made transoceanic flights routine. New navigation instruments, radar, de-icing devices, more reliable engines, modern transport planes and a better knowledge of flying conditions all over the world comprised the heritage that military aviation left to commercial carriers.

The decade saw military bombing advance from the feeble attempts of the B-10 trying to hit a target, to B-29s, operating in large masses, completely destroying large cities on a single mission. It saw air power built up from old bombers struggling to carry a 2,000-pound bomb 1,000 miles, to those carrying 7 tons of bombs to targets 1,600 miles away, and were still able to return to their bases; it saw the speed of fighters increase from 300 m.p.h. to more than 500 m.p.h.

New devices made it possible for bombers to fly equally well by night and by day, through all kinds of weather; made it possible for them to hit targets with practically the same precision in the clear, or when hidden by clouds and rain. The atomic bomb made its appearance, and, carried on a single plane, destroyed practically an entire city. New planes made their appearance—planes that could fly distances of more than 8,000 miles. New developments of rockets, manless planes, radar, remote control of flying planes, warheads that "home" on heat, light, sound and metal, were just around the corner; and man's imagination was strained with the thought of world-circling aerial giants in the offing. (H. H. A.)

U.S. Naval Aviation.—From its inception United States naval aviation included air components of the navy and marine corps. From Nov. 1941 to Jan. 1946, the coast

guard, including its aircraft units, operated under naval control. Liaison with the U.S. army air forces and with civilian agencies was maintained through membership on joint boards and committees.

Changes in organization between 1937 and 1946 were the result of the growing importance of air power in naval warfare. Under the chief of naval operations, a deputy chief of naval operations (air) was established in Aug. 1943 to handle questions of logistical and personnel planning for aviation and its co-ordination with other naval activities. The bureau of aeronautics continued to function as a material organization, charged with the design, development and procurement of aircraft and aviation material and with questions of maintenance and supply. On the highest departmental level was the assistant secretary of the navy for air.

Within the fleets air units were assigned to task forces for operations. For training, logistics, material and routine administration they came under type commands. In 1937, there existed a differentiation between carrier and patrol planes. Under war conditions, however, this proved confusing, and on Sept. 1, 1942, a single command for logistical support and administration was established in the Pacific fleet. The Atlantic fleet adopted a similar organization on Jan. 1, 1943. This system combined administrative centralization and stability with flexibility in operations.

Since marine aviation was an integral part of the naval aeronautical organization, its director was a subordinate of the deputy chief of naval operations (air), as well as of the commandant of the marine corps. Subordinate marine commanders reported to corresponding naval air commands for logistic and material activities, and marine units were assigned to task forces as their availability and the operating situation required.

The basic unit in all naval aviation continued to be the squadron. In 1937 patrol-plane squadrons with their tenders were organized in patrol wings, redesignated fleet air wings on Nov. 1, 1942, so as to include all navy landand tender-based aircraft, except lighter-than-air. In 1938 the navy created carrier air groups to include two or more squadrons operating from a single ship. The marine corps adopted a wing organization in 1941, each wing composed of two or more groups, and a group made up of two or more squadrons.

Beginning in 1934 as international relations began to deteriorate, the navy grew and aviation expanded even more rapidly than other parts of the naval establishment. Table I indicates the number of planes authorized at various dates either by legislation or executive order.

Table I.—Number of Planes Authorized (1934–44)

Date of Legislation or Executive Order	No. of Planes Authorized						
	Treaty Navy (estimated about 2,000 planes)						
May 17, 1938	"Not less than 3,000"						
June 14, 1940	4,500						
June 15, 1940	10,000						
July 19, 1940	15,000						
January 14, 1942	27,5 00						
June 15, 1943							
February 2, 1944							

In the state of the aircraft industry in 1946, authority to build a plane was no guarantee that it would be delivered within a short time, and the rate of expansion is better indicated by Tables II and III, the first of which gives the number of planes and pilots available on July 1 of each year, and the second of which traces the rise of the carrier force by calendar year.

The increasing number of planes and fliers was accompanied by the addition of ground personnel to main-

*Large carriers, 45,000 tons, were nearing completion when World War II ended.

tain and service the aircraft and to carry on administrative duties. The navy also bought, leased and built numerous facilities for training and support within the United States and began an advanced base program in both the Atlantic and Pacific. In the former area the transfer of destroyers to Great Britain in return for leases in the West Indies and the additional sites granted without compensation in Newfoundland and Bermuda permitted the construction of air stations which greatly increased the area brought under naval air surveillance.

Aircraft and Equipment.—Navy carrier planes were not simply standard military aircraft modified for carrier work, but were especially designed to meet the requirements of carrier operations. The bureau of aeronautics, working in close co-operation with research institutes and manufacturers, succeeded in designing and having built the finest carrier aircraft in the world, capable of meeting not only enemy ship-based but also all land-based planes encountered. On the basis of experience three typesfighters, scout or dive bombers and torpedo planes-were developed. The growth of the U.S. navy, the greater appropriations available from 1934 and advances in aeronautical science permitted the development of new models.. When war broke out in Dec. 1941, the basic designs had been drawn, and many new types either were being received in the fleet or were already in production. With modifications based on lessons learned in combat these basic models continued to be employed throughout the war period, and it was not until after the conclusion of hostilities that new types, designed during the conflict, became available. Table IV shows the carrier aircraft most widely used, the navy designation for each and the year in which it became operational.

Scout Bombers Dauntless										, ,	1941 1943
Torpedo Plane										TRF TRM	1942

Patrol planes made up a second category. Prior to Oct. 1941, the navy used flying boats exclusively for this sort of operation, having by that time the Catalina (PBY), the original model of which was delivered in 1937, and by 1945 had gone through six modifications including two am-

phibious versions; the Mariner (PBM), a two-engined plane, heavier, faster and with greater range than the Catalina; and the Coronado, (PB2Y) a four-motored flying boat used in antisubmarine warfare and, during the early part of the war, for transport rather than combat. Experience with the neutrality patrol between 1939 and 1941 showed that land planes were better suited to winter operation in northern latitudes, and in the autumn of 1941 the navy acquired 20 Hudson (PBO) bombers. From this plane descended the Ventura (PV-1) and the Harpoon (PV-2), employed in antisubmarine and antishipping attacks and in operations from the Aleutians. The first months of the war also demonstrated that a more easily defended and longer-ranged type was needed in areas where strong enemy opposition could be expected. Late in 1942 the navy obtained its first Liberators (army B-24s, which were redesignated PB4Ys) and which after extensive interior modification were used for search, reconnaissance and photographic work. A later version of this plane with a single fin and other changes to adapt it to naval requirements was given the more nautical name of Privateer (PB4Y-2). The marines employed another army model, the Mitchell (B-25, called by the Navy a PBJ).

Small single-engined seaplanes were developed for catapulting from battleships and cruisers. Standard military and civilian types were commonly employed in training and air transport. An exception was the giant Mars (JRM-1), a 70-ton flying boat, which was especially designed and produced for the navy.

The U.S. navy alone made large scale employment of lighter-than-air craft. Especially adapted to antisubmarine patrols, convoy escort and utility work, the blimps increased from a small force of 12 in Dec. 1941 to 135 capable of over-water operation in 1945.

Besides aircraft, the navy also developed instruments, equipment and ordnance. In many items standardization was achieved with the army and with Allied Powers. Machine guns, bomb types, radar and much electronic equipment were used by all. Among the contributions of the navy to the common stock were the Norden bomb sight, widely-used types of aircraft rockets, improved aerial torpedoes, and guided missiles. Some items such as sonobuoys and magnetic airborne detection gear, both employed in antisubmarine warfare, were not used by other services. The position of naval aviation made it possible to design plane types and equipment to meet the special problems of naval warfare. When items of use to other services were developed, continuous exchange of technical information made them rapidly available to all.

Training.-With a growing number of planes, training presented continuous problems of personnel, facilities and methods. Beginning with the Aviation Cadet act of 1935, congress provided for induction of large numbers of reserve officers. Because the cadets were brought into the service directly from civil life, they required instruction not only in the art of flying but also in naval subjects. Specialization was necessarily introduced and, instead of the naval aviator being drawn from the fleet and trained in all types of naval aircraft, there appeared large numbers of reserve officers qualified to fly only one type of aircraft and with a restricted knowledge of naval lore necessary to an understanding of their role in sea warfare. To relieve pilots of administrative and technical duties civilian specialists were commissioned as ground officers. In 1937, the navy possessed a single training establishment at Pensacola, Fla. By 1941 the two big bases at Corpus

Christi, Texas, and Jacksonville, Fla., had begun operation, and additional facilities were being constructed or leased in the interior of the country. To save on planes and to permit training to continue regardless of weather the navy adopted and, in thousands of instances, itself developed special training devices.

The leadership of the United States in naval aviation was recognized by its allies, and thousands of British, French and Latin-American pilots were given the navy's course of instruction.

Two years of war in Europe meant intensive preparation in the United States. Although the readiness of naval aviation was far from ideal, great strides had been made, planes had been designed and put in production, and the training program had rapidly expanded.

Wartime Functions.—Official policy indicated as a primary function of the U.S. navy, the control of the sea in defense of the nation and its interests. As an integral part of the naval forces, aviation contributed to this end in co-operation with surface vessels, submarines and marine ground troops.

Before World War II the role of aircraft in naval warfare was studied in the annual fleet exercises. Although the number of carriers and squadrons was small compared with later standards, on the basis of these annual manoeuvres the operating methods, tactics and military characteristics of aircraft were established, with such success that the plane types designed between 1935 and 1941 remained in use throughout the war.

Although the United States was not engaged in hostilities until Dec. 7, 1941, the navy went into action on Sept. 6, 1939, a week after the German invasion of Poland. It patrolled coastal approaches and sought to prevent the conflict from spreading to the western hemisphere. With the fall of France in the spring of 1940 and the acquisition of bases from the British in the autumn of the same year the tempo of the patrol increased and the search areas of naval aircraft were extended. In the spring of 1941 the passage of the Lend-Lease act virtually committed the U.S. navy to provide for the safety of convoys in coastal waters and for a considerable distance into the mid-Atlantic. By Dec. 1941, naval patrol planes were operating from Iceland, Newfoundland, Bermuda and the north coast of South America.

In the Atlantic theatre the navy had for its principal task the protection and maintenance of supply lines. Although carrier planes supported the landings in North Africa in Nov. 1942, and on the coast of southern France in Aug. 1944, the concentration of effort was against submarines which were threatening the convoys to England, North Africa and later the continent. Air participation at first was largely limited to planes operating from shore bases. Two types of patrol were maintained-an inshore patrol by light planes along the continental shelf and a widespread search pushed as far to sea as possible by big flying boats and land-based aircraft. From the beginning it was a co-operative venture in which the air forces of the United States, Great Britain, Canada, Mexico, Brazil and other belligerents participated. From Dec. 1941 until sufficient navy planes became available in the late summer of 1943, the U.S. army also assigned squadrons to antisubmarine duty to operate under naval control. From the latter date the navy assumed full responsibility for United States participation.

The best efforts of patrol aircraft, however, left an area in the mid-Atlantic free from air reconnaissance. Escort carriers converted from merchant hulls permitted the filling of this void after March 1943. Originally intended

to accompany convoys, these small carriers achieved more substantial results when operated independently as members of hunter-killer groups, composed of a single carrier and a small number of co-operating destroyers or destroyer escorts. Combined air-surface action proved the best weapon against the submarine.

Naval planes accounted for 81 German and 1 Italian submarine, about 10% of those sunk by all forces in the Atlantic. Figures, however, told only a small part of the story. Since the real objective of the navy was to get ships with men, equipment and supplies to the European theatre, the number of submarines prevented from attacking while convoys slipped past was as important as the actual kills. The increase in planes and escort carriers was accompanied by a decline in the effectiveness of axis underwater operations. In this respect aviation contributed significantly to the naval effort.

In discussing the Pacific theatre the U.S. Strategic Bombing survey remarked:

Japan's geographical situation determined that the Pacific war should in large measure be a war for control of the sea and, to insure control of the sea, for control of the air over it. As a result, attacks against warships and merchant ships and amphibious operations for possession of island positions on which forward bases could be located were close to the heart of the struggle. Carrier task forces, surface ships to provide logistic support, and submarines therefore assumed roles of unusual importance. (U.S. Strategic Bombing Survey, Summary Report [Pacific War], p. 27, 1946.)

It was primarily a naval war, because, if Allied military power were to count, it must be carried across the ocean and, before that could be done, the Japanese fleet had to be destroyed, Japanese forces driven from key island positions, Japanese supply lines disrupted, and by-passed Japanese garrisons contained. Early in the war it was discovered that ships could not safely operate unless friendly forces controlled the air. Because long over-water distances combined with the range limitations of aircraft made support by land-based air impossible in many vital areas, naval aviation was a key to victory in the Pacific.

Among numerous actions six major naval engagements could be distinguished: Battle of the Coral sea, May 5-8, 1942; Midway, June 3-6, 1942; Guadalcanal, Nov. 12-14, 1942; the Philippine sea, June 19-20, 1944; Leyte gulf, Oct. 23-26, 1944; and the East China sea, April 7, 1945. In four of these surface craft never made contact, and the entire battle was an air-surface engagement between carrier planes. In the battle of Guadalcanal land-based naval and marine aircraft played a major role; and in the battle for Leyte gulf, carrier.planes turned back two enemy forces and pursued the remnant of a third that survived a surface engagement in Surigao strait. Besides the war vessels destroyed in major actions, others were sunk in lesser encounters and in the harbours of Japan and its empire. All in all, naval and marine aircraft accounted for 48% of the Japanese combatant ships of the size of destroyer and above sunk during World War II.

A second effort was to destroy the merchant shipping through which the Japanese obtained supplies from the East Indies. Naval, including marine, air units accounted for 20.6% of this shipping, twice as much as any other agent except United States submarines. Many of the cargo vessels sunk were encountered by naval planes in the course of routine patrols from Pacific island bases. Effective night tactics against shipping worked out by radarequipped Catalinas, known as Black Cats, were employed in the South and Southwest Pacific.

Amphibious operations on a scale unprecedented in warfare were a feature of the struggle in the Pacific. In

the successful storming of Japanese beaches naval aircraft from carriers played a conspicuous part, especially in the advance of Central Pacific forces from the Gilbert Islands, Nov. 1943, to Okinawa, April-June 1945. No amphibious operation could succeed without control of the air, and where distance from Allied land bases was greater than 300 miles, necessary air cover could come only from carriers. Fast carrier forces destroyed air power in the region under attack, prevented the Japanese from bringing up reinforcements either through the air or on the surface, and, when needed, gave close support to landing troops. The last function was more particularly attributed to escort carriers that accompanied the invasion force, covered its ships and furnished antisubmarine protection as well. Marine aircraft continued the support of ground troops by operating from captured Japanese fields as soon as they were secured. In the closing months of the war marine squadrons from escort carriers furnished close air support for landings.

Japanese garrisons left on by-passed islands were prevented from harassing Allied communications by regular air attacks destined to render air fields inoperational, destroy installations and lower morale. Marine airmen were particularly active in this work, but navy and army fliers also participated.

Exact figures on the number of Japanese aircraft destroyed during the war will probably never be ascertained. The best figures available in 1946, however, indicated that naval and marine planes accounted for about three-fifths of those shot down or destroyed on the ground in all theatres, and, therefore, constituted the largest single factor in the destruction of Japanese air power.

The acquisition of bases from Great Britain in 1940 and the extension of U.S. installations in the Pacific emphasized the need for an air transport system to move high-priority cargo and personnel. On Dec. 12, 1941, the naval air transport service was established. At its greatest extent it operated over 76,000 mi. of regularly scheduled air lines, reaching from Europe to the shores of Asia and entering all theatres where the navy operated. In forward areas in South and Central Pacific, army, navy and marine corps pooled their aircraft and facilities and operated together under marine control.

Postwar Developments.—The end of hostilities in Aug. 1945 resulted in an immediate cancellation of orders for planes. The process of building the air force was reversed, planes were scrapped, personnel were demobilized, air fields were sold or returned to their civilian owners or leased, carriers were put up and the aeronautical organization in general was restored to a peacetime footing. By late 1946 demobilization was virtually terminated, and naval aviation had approximately 16,000 pilots and a similar number of planes. Of the great carrier force, between 20 and 25 were to be retained in the active fleets, three others in the reserve fleet, and 78 preserved and assigned to the inactive fleet. The naval air transport service abandoned its transatlantic routes and curtailed those in other areas, except in the far reaches of the Pacific, where some extension occurred to serve the occupation forces in China and Japan.

Not all construction was stopped at the end of the war. Carriers of a new large type, designated CVB, were placed in commission late in 1945. Aircraft squadrons were reequipped with planes embodying the lessons learned and advances made during the war. Most widely noted of the new aircraft was the Neptune (P2V), a two-engined patrol

plane that in Oct. 1946 set a record for air-line distance for any plane type when one flew from Perth, Australia, to Columbus, Ohio, a distance of more than 11,000 mi. On the basis of the war experience, the navy embarked on an extensive program of experimentation and development. Jet propulsion presented many problems, especially in adapting it to the peculiar conditions of carrier operation. On July 21, 1946, however, a navy-designed jet plane landed on, and took off from, the "Franklin D. Roosevelt." In the form of target drones for anti-aircraft practice, the navy employed pilotless aircraft during the war, and experimentally they were used in operations near the end of the conflict. After the termination of hostilities the investigation of their relation to all phases of naval warfare progressed rapidly. In electronics research went forward along many lines, much of it in close co-operation with the army, civilian agencies of government and leading research institutions.

To ensure rapid mobilization in case of national emergency a reserve program was established under which former naval and marine fliers enjoyed the opportunity to fly at regular intervals and to receive instruction in new developments and tactics. Provision also was made for training young men for the reserve so that the nation might be assured of a continuing group of qualified naval aviators available when needed. (A. W. Rd.)

Avila Camacho, Manuel

Avila Camacho (1897—), Mexican statesman, was born April 24, 1897, at Teziutlán in the Mexican state of Puebla. He joined the successful revolution against Victoriano Huerta in 1914, attaining the rank of a general of a division. Avila Camacho was minister of war and navy in the Rodriguez government and was secretary of national defense in the cabinet of President Lázaro Cárdenas. As Cárdenas' choice as his successor to the presidency, Avila Camacho was elected president on July 7, 1940, defeating Gen. Juan Andreu Almazán by 2,476,641 votes to 151,101. Avila Camacho was inaugurated Dec. 1, 1940.

One of his major acts was settlement of the oil expropriation controversy in 1941. In foreign affairs, Avila Camacho consistently stressed hemispheric solidarity and on May 22, 1942, three weeks after a German submarine had sunk a Mexican ship, he called for war against the axis. Congress unanimously approved his request; on June 2, 1942, he signed Mexico's declaration of war against Germany, Italy and Japan (retroactive to May

22), and Mexico joined the United Nations. Under his guidance, Mexico embarked on a program of developing war materials and supplied many vital raw materials to U.S. factories during the conflict.

Avila Camacho did not neglect cultural activities during the war, and in 1944 he signed a decree requiring every Mexican to learn to read and write by Feb. 28, 1946. Some 10,000,000 primers were printed in this sweeping effort to stamp out illiteracy. Avila Camacho stepped down as President Dec. 1, 1946, in favour of his successor, Miguel Alemán.

Azaña y Diez, Manuel

Azaña (1880-1940), Spanish statesman, was born in Alcala de los Henares in Castile on Jan. 10, 1880. He was educated at the Augustinian academy at El Escorial and began his career as a playwright and author. For 12 years he was secretary of a literary society in Madrid, during which he won fame as a critic. He was indifferent to politics until the establishment of the Spanish republic in 1931, at which time he became minister of war in the provisional cabinet. His army reforms were unpopular with the regular officers and were credited in many quarters as being a major cause for the revolt led by General Franco in 1936. When Niceto Alcala Zamora was deposed as president in 1936, Azaña was chosen to succeed him. In Nov. 1936, the insurgents' advance on Madrid caused him to flee to Barcelona, and he moved with his cabinet from place to place until it was apparent that the republican cause was lost. He then went to Paris and took refuge in the Spanish embassy. He died Nov. 4, 1940, at Montauban, France.

Bacon

The output of U.S. bacon during the decade 1937-46 maintained about the usual relation to total pork production, approximately 19% of total dressed weight. The amount produced depended upon the practice followed in trimming dressed pork. Consumers in the United States and Great Britain continued to prefer a lean bacon with very little fat, while the Russians wished all the fat they could get. That part of the pork output used for lendlease shipments was cut in accord with these preferences. While the amount of bacon sliced under federal inspection indicated the general trend, it was not a wholly accurate guide to the amount produced. In 1937 this amounted to only 219,541,000 lb., while estimates based on the 19% ratio of bacon to dressed pork would indicate that total production was about 1,321,000,000 lb. The sliced product probably represented the changes in the supply available to civilians fairly accurately, however. By 1942, pork production had increased in volume about 50%, while inspected bacon output increased to 365,749,-

ooo lb. Pork production reached its peak in 1943, but inspected bacon was at the top, 549,857,000 lb. in 1944. The hogs marketed in 1944 were lighter than those sold in 1943, which accounted for the smaller output of bacon.

Production of Bacon in the United States, 1937-46

				(in po	ounds)				
1937				1,321,000,000	1942				2,037,000,000
1938					1943				
1939 1940				1,645,000,000	1944				
				1,892,000,000 1,795,000,000	1945 1946				

Supply for civilians was very scarce in 1944 and 1945. Exports of bacon and sides declined from 38,400,000 lb. in 1931 to 2,900,000 lb. in 1937 then increased to 203,400,000 lb. in 1942. Then followed a decline to about 40,000,000 lb. in 1945.

With the beginning of World War II, Canada made "bacon agreements" with Great Britain to supply that market. The agreement made in 1942 called for exports from Canada amounting to 675,000,000 lb. A considerable part of the U.S. bacon supply was required for the military forces, and a shortage of civilian supplies resulted. Government purchases declined sharply in 1945, however, allowing more of the production to go into civilian markets. By mid-1946 bacon distribution had almost reached the prewar normal. Bacteriological Warfare

See BIOLOGICAL WARFARE.

Bacteriology

An evolution of knowledge of antibiotics occurred during the decade 1937-46. Noteworthy advances in knowledge of penicillin had begun in 1936, when a group of scientists at Oxford university, England, with aid from the Rockefeller foundation and under the direction of Howard Florey, began exhaustive investigations of penicillin, which had first been observed by Alexander Fleming in 1929. Between 1937 and 1946 the methods of mass manufacture, artificial development of better types of culture variant and culture media, methods of assay and of therapeutic administration and numerous other technical details were greatly improved. While laboratory studies by thousands of workers throughout the world were proceeding, clinical trials were being made, resulting in cure after cure of hitherto highly fatal or disabling infectious diseases, including gonorrhoea and syphilis. Under the impetus of the war in Europe and the subsequent Pearl Harbor attack in 1941, and with the guidance and help of the Food and Drug administration, the U.S. Office of Scientific Research and Development and the National Research council, work on penicillin was speeded up and broadened, especially at the Northern Regional Research laboratories at Peoria, Ill. Eventually these studies led to the commercial production of penicillin on a scale so vast that whole industries sprang into being. It was not too much to say that the course of World War II and the whole attitude of modern society toward questions relative to venereal diseases, sex, promiscuity and morals were appreciably influenced within the span of two years by the production and use of penicillin for the control of war wound infections, epidemic disease and especially venereal disease.

The product was made purer and more concentrated, and in 1944 the International Conference on the Standardization of Penicillin at London agreed on standards of potency, definition of an international unit and methods

of assay. In 1944 and 1945, the efficacy of the drug appeared to diminish mysteriously, but extensive studies at Johns Hopkins university, Baltimore, Md., the U.S. public health service and elsewhere indicated the solution of the mystery as a change in character of penicillin. In 1946 appeared the results of ten years of the most intensive and confidential chemical studies of penicillin. It was revealed by these combined clinical and chemical studies that several substances, among them penicillins G, F, X and K, all chemically much alike, were produced in varying proportions by various strains of Penicillin notatum under different growth conditions. Some of these products, like penicillin K, were shown to be less effective than others, especially in the treatment of syphilis and, when inadvertently present in the commercial product, with compensatory diminution of more effective penicillins such as X and G, caused the clinical failures previously mentioned that were so discouraging before the nature of the different penicillins was discovered.

While the dramatic history of penicillin was being evolved, parallel work was carried on by bacteriologists seeking substances similar to penicillin but of bacterial origin. Many bacteriotoxic substances of microbial origin similar to penicillin were announced during 1937–46, among them bacitracin, subtilin and clavacin.

The Rockefeller institute in New York announced in 1939 the discovery of a substance (tyrothricin) in cultures of a soil bacterium (B. brevis) from which two other substances (gramicidin and tyrocidin) were later separated. Their action was found to be roughly similar to that of penicillin. However, after much clinical trial during 1940–44, these proved to be too toxic for injection, although it was found that they could be used for local application.

In 1944, scientists at Rutgers university, New Brunswick, N.J., discovered a substance analogous in many ways to penicillin, but produced by a mouldlike bacterium from soil, Actinomyces griseus. They called the substance streptomycin. In the two years after this discovery, the history of streptomycin underwent an evolution somewhat like that of penicillin, but with much of the way cleared by knowledge already gained in developing the latter drug. Improvements in methods of cultivation looking to greater yield, better means of concentration and purification, chemical analysis, and methods of assay and standardization were all worked out in 1944 and 1945. Clinical trials kept pace, and it was found that streptomycin, like penicillin, is relatively atoxic on injection. Streptomycin promised to be of use in several infections, notably tuberculosis, typhoid, brucellosis and some other diseases caused by gram-negative bacilli, not amenable to penicillin treatment. However, information was still very incomplete in 1946, and early enthusiasms over new drugs had repeatedly been found premature.

Bacterial Variation.—Interesting corollaries of these developments were discoveries and applications of new knowledge of the phenomenon of bacterial variation. It was found in 1940 and later that many bacteria, notably gonococci in the presence of doses of sulfa drugs not sufficient to destroy them at once, adjusted themselves to the sulfa drugs and survived, *i.e.*, the bacteria became drug resistant, or drug fast. The surviving bacteria could then cause gonorrhoea and other infections in spite of sulfa-drug therapy. Soon it appeared that the original drug-susceptible gonococci, and other susceptible bacteria among the population were being replaced by drug-fast strains, thus throwing shadows of doubt over the bright hopes for con-

trol of gonorrhoeal and other infections by means of the sulfa drugs. In 1945 and 1946, similar shadows appeared to darken the future for drugs like penicillin and streptomycin.

In another field the phenomenon of bacterial variation dispelled shadows, a dramatic example being the development of yellow fever vaccine. This story had its roots in the Afro-American slave trade which introduced yellow fever to the Americas. Walter Reed and his companions at the turn of the century revealed the aetiological agent and vector of yellow fever. It remained for scientists of the international health division of the Rockefeller foundation and the Departamento Nacional de Saude Publica of Brazil to develop during the 1937-46 decade an apparently safe and very effective yellow fever vaccine. By 1936, yellow fever virus had been biologically modified for vaccine by propagation first in the brains of mice (1932) and then (1936) by maintenance in tissue cultures so that it was of reduced viscerotropic but of normal neurotropic virulence. Vaccines made with these virus variants required the concomitant use of immune human or animal serum as a safety measure. In 1937, a further mutation occurred in the tissue-culture virus resulting in low neurotropic as well as low viscerotropic virulence. Vaccine prepared with this virus (called 17D) required no immune serum. The use of such material (17D virus) as a vaccine for public use against yellow fever was immediately begun in Brazil and West Africa. Later in that year, it was found that the 17D virus could be propagated on a large scale in whole, living, chick embryos in the egg, and vaccine was then prepared from inoculated eggs by suitable preparation of the chick embryos and suspension of the product in normal human serum. Such vaccine was found very effective and by 1942 had been used to vaccinate hundreds of thousands of persons in Brazil and elsewhere with only a few untoward results. Some of the persons vaccinated, especially with certain lots of vaccine, had developed jaundice (1939) and some an encephalitis. It was suggested that the results were not caused by the 17D virus itself, but might be the result of a contaminating virus in the human serum. However, experimental evidence at the time did not prove this. In 1941, in view of the probability that U.S. troops would be exposed to yellow fever, it was decided to immunize them with the vaccine. At the Rockefeller institute in New York, huge egg incubators and other facilities were established, large numbers of human blood-serum volunteers were called, and great quantities of the vaccine were prepared and injected into U.S. military personnel. After the appearance of numerous cases of icterus and some deaths, an extensive investigation in 1944 revealed that the agent responsible for the jaundice appeared to be a hitherto unknown filterable virus pathogenic for human beings and sometimes appearing in the blood of donors without producing symptoms. It became evident that the jaundice-producing principle had gained access to the vaccine by way of the serum, obtained from donors who were supposedly normal, and used in manufacture. Vaccine was afterward prepared without human serum and caused no jaundice.

Thus a new disease, called homologous serum jaundice, that probably would not otherwise have been recognized for years, was discovered, and the dangers of injection of human serum into human beings, a fairly general practice for some purposes, were revealed.

Epidemic jaundice still occurred among troops, however, and it was clear that there existed still another type of little understood disease producing a clinically similar picture. Field, laboratory and clinical investigations reported by members of the U.S. army medical corps and many other scientists, in 1944-46, resulted in a brilliant elucidation of the hitherto hazy relationships between homologous serum jaundice and the clinically similar diseases called infectious hepatitis, caused by a totally different agent and epidemiologically and immunologically wholly distinct. Infectious hepatitis was shown in 1945 and 1946 to be probably faecesborne.

Many other interesting reports appeared on bacterial variation during the decade. For example, it was demonstrated that the virus of fox encephalitis, cause of costly epidemics on fur ranches, could be diminished in virulence for foxes by passage through ferrets. An entirely successful living vaccine, preventing hundreds of thousands of dollars loss to fox fur ranchers, resulted.

In 1941, other scientists of the U.S. army medical corps summarized several years of studies dealing with changes in virulence of typhoid bacilli and the relation of these changes to the potency of prophylactic typhoid vaccines. They developed a typhoid vaccine for U.S. troops which was apparently far more effective than vaccines formerly used. It was later shown that after once receiving the usual preliminary series of three injections of typhoid vaccine, an annual injection of 0.1 ml. intradermally (a dose causing only a slight local swelling) maintained immunity at a protective level.

Still another application of knowledge of bacterial variation was made in the development of an effective antipertussis vaccine, former vaccines having been disapproved by the American Medical association because of their ineffectiveness. In 1936 it was already known that freshly isolated pertussis bacilli are, like freshly isolated typhoid bacilli, smooth and virulent (called Phase I) and that on cultivation on any but Bordet-Gengou or equivalent media, they undergo degenerative variations resulting in saprophytism and R forms. In 1939, it was shown at the University of Virginia, Charlottesville, Va., that pertussis vaccines made from smooth (Phase I) variants are far better, as measured by mouse protection tests, than vaccine made with the saprophytic variants. Evidence was also presented indicating that discredited pertussis vaccines had probably been made with saprophytic variants. These were important observations because a great controversy had raged over the possible effectiveness of pertussis vaccine. Favourable results were obtained with pertussis vaccination by members of the Michigan state department of health (1936 and later), but these were in direct contrast with the negative results of other workers at Northwestern university (1936). No explanation for the difference had been found satisfactory by the end of the decade. Extensive investigations of pertussis vaccination were made by many workers in the United States and other countries during the decade before 1946, nearly all of which were favourable to the vaccine in some degree. The net result was the demonstration that pertussis vaccine is fairly effective for human vaccination if prepared with the Phase I variant of H. pertussis. In 1943, the Committee on Therapeutic Procedures for Acute Infectious Diseases and on Biology of the American Academy of Pediatrics recommended immunization against pertussis as a routine procedure, while in 1944 the Council on Pharmacy and Chemistry of the American Medical association voted to reconsider H. pertussis vaccine for inclusion in "New and Non-Official Remedies."

Another proof, and one of the most fundamentally significant demonstrations of the marvellous possibilities in bacterial variation, was given in the discovery in 1936 at the University of Rochester, Rochester, N.Y., that the

virus of rabbit fibroma, a disease peculiar to wild labbits, could be transformed so that it possessed all the properties of the virus of infectious myxomatosis, a related but quite different disease occurring only in domestic rabbits. The change could be induced by injecting into rabbits the fibroma virus mixed with heat-killed myxoma virus. The animals died with myxomatosis. The nature of the alteration in the fibroma virus was not elucidated, but a later series of researches of the most profound character, in transformations of pneumococcus types, revealed the possible mechanism and pointed the way to numerous exciting discoveries in the fields of cell physiology, the nature of genetic change, the nature of viruses, the cause of malignant growths and others.

These latter researches had their origin in a previous discovery that mice died of type III pneumococcus infections after being injected with a certain dose of living, non-typespecific, nonvirulent, rough pneumococci derived from type II, incapable of causing an infection, but mixed with heat-killed cells of virulent, smooth, type III pneumococci, which were also innocuous. It was later shown not only that the same alteration could be induced by similar mixtures in vitro, but that Berkefeld filtrates of extracts of dead cells of one type would confer permanently their virulence and type specificity on living, non-type-specific, nonvirulent, rough cells derived from another type. In 1944, a brilliant light was thrown on the mechanism involved in these transformations by scientists of the Rockefeller institute at New York when they isolated from the dead, type-III-specific cells a form of desoxyribonucleic acid of which so small an amount as 0.003 mg. in 2 ml., i.e., in dilution of 1:600 million, would induce genetically stable smoothness, virulence and type III specificity in living, non-type-specific, rough, nonvirulent type II-derived cells. Implications pointed out by the discoverers were that living entities, in this case pneumococci, could be treated under known conditions with a known substance so as to produce not only a predictable, permanently hereditable alteration in metabolism and growth characters, but a continued multiplication of the determinative chemical substance itself, as part of the new cells. Interesting inferences were drawn regarding mechanisms of heredity; the cause of cancers, which appear to result also from hereditable alterations in metabolism and growth characters of certain body cells; and the nature of viruses.

Microscopy.—The field of microscopy was also exceedingly active during the decade. About the beginning of the decade, the use of the short-wave length of electrons as a substitute for light in microscopes in which the glass lenses were replaced with circular electromagnets of variable strength, opened the way to magnifications and discoveries of minute structural details of bacteria and viruses and many other minute things never heretofore dreamed of. Starting from original work in 1935, and developed during the ensuing decade at the R.C.A. laboratories, the first announcements of a practical electron microscope of high power came in 1939 and 1940. Numerous scientists at the R.C.A. laboratories at Camden, N.J., the University of Pennsylvania, Philadelphia, Pa., and elsewhere made use of these instruments to reveal such details of bacteria as intercellular protoplasmic bridges between cocci and bacilli in chains, details of the cell walls of various bacteria, the relation of capsule to cell wall in pneumococci, various structural differentiations within the protoplasm of bacterial cells, the details concerning the combinations of various types of antigens and antibodies, hitherto unseen flagella on syphilis spirochetes, the "tadpole" configuration and internal structure and mode of action of certain

bacteriophages, the size and structure of smallpox, influenza, tobacco mosaic and other viruses and many other details.

An important improvement in technique was added in 1945 and 1946, when it was found at the University of Michigan, Ann Arbor, Mich., that by depositing obliquely an extremely thin coating of metallic vapour (chromium or gold) on films prepared for electron microscopy, the objects on films so coated appeared to cast shadows, giving pictures with startling sharpness of outline and almost three-dimensional in effect. These permitted the measurement of heights of objects photographed on flat surfaces, and revealed topographic and structural details not otherwise visible.

Other Bacteriological Advances.—In the war against venereal diseases, tremendous advances were made in development of laboratory procedures which contributed heavily to the development in penicillin treatment. Methods of preserving syphilis spirochetes for experimental purposes over periods of years by maintaining them at extremely low temperatures (-76°C.) were perfected at the Johns Hopkins School of Hygiene and Public Health. It was shown in the same laboratories that the danger of syphilis from blood-bank blood or dried plasma is negligible. Important new concepts of the biology of syphilitic infection and of the relationships between various related spirochetal diseases like yaws and "rabbit syphilis" were developed by the same workers.

The bacteriological history of the decade 1937-46 included many other discoveries of far-reaching significance. Much light was thrown on problems of bacterial metabolism, leading among other things to the development for various bacteria of culture media composed entirely of pure chemicals; bacteriological methods of vitamin assay; knowledge of carbon assimilation by the use of radioactive carbon; and knowledge of fermentation processes of great industrial value. Other important and interesting discoveries were the existence of a nonantitoxic form of immunity against diphtheria; the production of a practical vaccine against typhus fever by cultivation of the rickettsiae in the yolk of living chick embryos, which aided in Allied victories in Italy and elsewhere; observations on the occurrence of poliomyelitis virus in human faeces and its survival in flies, suggesting possible modes of transmission. and many others. Of utmost importance also were studies carried out in various parts of the U.S. during 1942-45 by the U.S. army medical corps in co-operation with the University of Minnesota, the University of California, the State University of Iowa, the Rockeseller foundation, the University of Michigan, Cornell university and others, which resulted in the demonstration by field trials, of a vaccine which confers on human beings resistance to two types of influenza virus. Development of the vaccine itself and evaluation of its antigenicity were greatly facilitated by the discovery in 1941 at the Rockefeller institute in New York that the erythrocytes of chicks are quantitatively agglutinated by the virus and that influenza immune bodies inhibit this agglutination in proportion to their concentration.

Mention must also be made of extensive studies made chiefly by the army medical corps on Q fever, a respiratory disease of rickettsial aetiology, which suggested it's wide-spread distribution and the importance of the disease, formerly obscure and almost unknown in the U.S. as late as 1946.

Another rickettsial disease little known in the U.S.,

tsutsugamushi or mite typhus, and brought into new prominence by its occurrence in U.S. troops in Pacific islands, was fully revealed in its aetiological, ecological, clinical, epidemiological and other relationships as a result of brilliant investigations partly carried out under fire by the United States of America Typhus commission.

In Nov. 1946, the long-anticipated announcement of the synthesis of benzylpenicillin was made, and unequivocal proof of the fact that it is identical with the natural product was given. (See also Chemotherapy; Epidemics and Public Health Control; Medicine.)

Badminton

Least exacting of the racquet games, badminton experienced unusual growth during the decade 1937-46 in both popularity and calibre of competition. It was played extensively in all sectors of the United States except the deep south, as well as in Canada, Australia, Denmark, England, France, India, New Zealand, Mexico and Sweden.

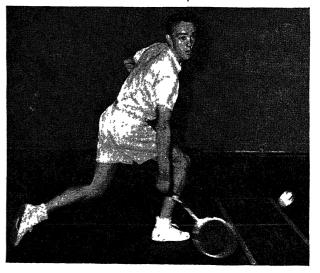

The shuttlecock sport produced one of the most dominant of all sports champions in David Guthrie Freeman, who from 1939 until 1942 won four successive men's singles titles. A tennis, ping-pong and squash player of note, Freeman had no equal after taking over the badminton crown in 1939. After service in the armed forces, Freeman returned to the game in 1946 with a domination of California sectional championships.

Of the six national championships held during the decade, the coveted men's singles title was held by only two players—Freeman and Walter Kramer of Detroit, Mich. Kramer won the championships in 1937 and 1938, after which Freeman brought the title to Pasadena, Calif. each year it was contested. He also shared the men's and mixed doubles championships from 1940 to 1942.

Badminton experienced a four-year recess in U.S. national tournament competition from 1943 through 1946. The various badminton associations, however, carried on with sectional tournaments. The game suffered even more acutely in other countries, with most national championships abandoned for the duration as early as 1939. Duration champions in men's and women's singles, including the last year they won their titles, were as follows: Australia-R. J. Harper and Mrs. H. B. Wray, 1939; Canada-James Snyder and Mrs. W. R. Walton, Jr., 1940; Denmark –Tage Madsen and Miss Tonni Olsen, 1939; France–Henri Pellizza and Mlle. Y. Girard, 1940; India-Daviner Mohan and Miss T. Deodhar, 1944; Malaya-Wong Peng Soon and Miss Lee CeeNeo, 1941; Mexico-F. Martinez Rico and Mrs. Norma Krafft, 1939; New Zealand-R. H. Lewis and Miss Mavis L. Kerr, 1939; Sweden-Haase Peterson and Miss Martha Holmstrom, 1942.

With Freeman topping the men's field, California added

Dave Freeman won his fourth straight U.S. badminton singles championship at Montclair, N.J., April 4, 1942, establishing an unequalled record for the decade 1937–46. He is shown at a practice match at Duke university

further to its prestige as a badminton centre by dominating women's competition. Evelyn Boldrick of San Diego became the second two-time national women's champion, winning the titles in 1940 and 1942. Mrs. Del Barkhuff of Seattle, Wash., won the titles in 1937 and 1938. Thelma Scovil and Janet Wright of San Francisco stepped to the fore in California wartime tournaments.

Tournament badminton received its impetus with

the formation of the American Badminton association in 1936, its membership growing from 155 clubs to 229 in its second year. The association and associate members sponsored 40 sectional tournaments during 1938.

1943-46-No championships held

The year 1939 marked the downfall of Jack Purcell of Canada, long-standing star of the professional field and the rise of Bill Markham, New York pro; it also brought Freeman into championship ascendancy. Having won the national singles in 1939, Freeman extended his laurels into men's and mixed doubles and became the duration champion in all three events. He teamed with Chester Goss of Los Angeles to win the men's doubles in 1940–41–42, and joined Sara Williams of Spokane, Wash., to win the mixed doubles over the same period.

Carl Loveday of Montclair, N.J., replaced Kramer as Freeman's chief singles opposition in 1941 and 1942, but it made no difference. Freeman defeated Loveday, 15-5, 15-10, in the singles championship final of 1942, after which World War II forced postponement of all U.S. national events. The game was restricted to sectional tournaments during the war, with Loveday dominating play in the east during 1943. Richard Casey of St. Louis captured the midwest singles title, with Pearl Peterson of Detroit the sector's leading feminine player. Helen Noble and LeRoy Erickson, both of Pasadena, topped Pacific coast competition in 1943.

Casey continued as midwest champion in 1944, and Eleanor Coambs of Chicago replaced Miss Peterson as women's titlist. Janet Wright and Erickson won both the southern and northern California singles during 1944. The former continued to dominate Pacific coast women's play in 1945, winning both the northern and southern California titles and bowing only to Helen Noble of Pasadena in the Pacific southwest singles. Bernard McCay of Pasadena also won two out of California's three major tournaments. Players from St. Louis, Mo., dominated the midwest championships, with Casey capturing his third singles title. Marie Bytnor, also of St. Louis, won the women's singles championship. Eastern competition throughout the war years was restricted principally to doubles.

Freeman returned to civilian life to dominate every badminton tournament he entered in 1946. He won both the northern and southern California singles, defeating a fellow Pasadena player, Barney McCay in each final. Freeman won the northern title, 15-12, 15-11, and the southern title, 15-5, 15-1. Thelma Scovil of San Francisco won the southern California women's crown, while Shirley Blanchet captured the northern crown.

Loveday dominated play in the east, with singles vic-

Badoglio, Pietro

Badoglio (1871–), Italian army officer, was born Sept. 28, 1871, at Grazzano Monferrato, Piedmont. He saw service in the Eritrean campaign of 1896-97, and served in World War I, from which he emerged as a general. He was elected a senator in 1919 and was made chief of the army general staff in 1925. He was created Marchese del Sabotino in 1928 and served as governor general of Libya, 1928-33. He participated in the Ethiopian campaign and in 1936 was named viceroy of Abyssinia. He later resigned as viceroy and was created duke of Addis Ababa. Following Mussolini's declaration of war against the Allies in June 1940, Marshal Badoglio assumed command of all Italian armed forces. Made the scapegoat for the failure of the Italian invasion of Greece, he resigned as chief of the general staff "at his own request," (Dec. 6, 1941). Eighteen months later, Badoglio emerged from obscurity to become premier, July 25, 1943, after Mussolini's ouster. On Sept. 3, the marshal concluded a secret military armistice with Gen. Eisenhower and five days later (Sept. 8), Badoglio told the Italian people that he had signed the Allied unconditional surrender terms. On Oct. 13, 1943, he declared war against Germany, and Italy joined the Allies as a co-belligerent. After the liberation of Rome, Badoglio stepped down as premier and was succeeded by Ivanoe Bonomi, June 9, 1944. At the Nuernberg trial, secret documents were introduced in evidence (Feb. 2, 1946), which said Marshal Badoglio was a member of a world-wide anti-Hitler group behind the bombing attempt on Hitler's life in July 1944.

Bagramyan, Ivan C.

Bagramyan (1895?—), Russian army officer, was born in Gyandzak, near Kirov-Abad, of Russian-Armenian parentage. An officer in the Czarist army, he joined the Red army during the revolution and was with a cavalry regiment of the Armenian division. He was appointed regimental commander in 1924 and in 1930 entered Frunze

Military academy at Moscow. After graduation, he continued his military studies in the General Staff academy, where he later served as instructor for three years. When Germany invaded the soviet union in June 1941, Bagramyan was serving in the Ukraine. He participated in the Russian victories at Kharkov, Kursk and Vitebsk and was promoted to the rank of lieutenant general and assistant chief of staff. In 1943, he commanded the 1st Baltic army which breached the German lines at Nevel and in Sept. 1944, the 1st Baltic army participated in the soviet offensive below Riga. Stalin promoted him to colonel general and he was awarded the Order of Kutuzov, first degree.

Bahamas

The Bahamas, an archipelago of about 3,000 islands, islets (or cays) and rocks, east of Florida and north of Cuba, extend about 800 mi. in length, lying between 21° and 27° N. latitude and 72° and 79° W. longitude. The islands are organized politically as a British colony and are generally considered as part of the British West Indies. The capital and only city is Nassau (pop. 19,756). Area: 4,403.5 sq.mi.; pop. (1943 census): 68,846 of whom 29,391 were on the island of New Providence. The population by the 1931 census was 59,828; official estimates in 1939 placed it at 67,729 and in 1940 at 66,219. The racial distribution was about 87% Negro and 13% white, chiefly of British origin. The population density of New Providence Island, by the 1943 census, was more than 500 per sq.mi; that of the remaining islands was less than 16 per sq.mi. The constitution of the crown colony (granted in 1728) provided for a legislative council of nine crown-appointed members, a house of assembly of 29 members elected by 15 districts, and a crown-appointed governor aided by an executive council of not more than nine, Governors during the decade 1937-46: Sir Bede Clifford, until May 1937; Sir C. C. F. Dundas, May 1937-July 9, 1940; H.R.H. the Duke of Windsor, July 9, 1940-July 28, 1945; William L. Murphy, after July 28, 1945.

the years 1937-46 was the readjustment of the islands to wartime conditions and problems, both political and economic. The tourist trade had always been an essential factor in the economy of the archipelago, and tourists in 1937 reached the peak number of 57,765. This number tended to decline rapidly thereafter, especially after the outbreak of World War II, and as early as 1938 the colonial government was taking steps to increase the tourist trade; action was taken at that time to welcome "ship-hotels." In a further effort to encourage tourist traffic, the government in 1939 waived passport regulations. By 1941 the declining number of tourists had forced the closing of many hotels; only 25,000 tourists were estimated to have visited the islands in that year, spending an estimated \$4,000,000 in the colony. Tourist trade continued to drop sharply in 1942 and later war years; by 1943 tourists numbered only 3,652. By the end of 1945 this mainstay of Bahamian economy was improving, however, especially

THE PRINCIPAL factor in Bahamian development during

Labour difficulties of various sorts occurred during the decade. A serious and spectacular riotous outbreak took place on Great Inagua, the southernmost large island, in Aug. 1937, during the course of which one person was killed and 15 deported by the rioters. On the night of

with the expansion of air services to Nassau from New

York and Miami.

Duke of Windsor, then governor of the Bahamas, and the duchess greeting crowds in Chicago as they were en route to Calgary, Canada, in Sept. 1941

May 31, 1942, serious rioting broke out in New Providence as the result of a labour dispute. Two of the 88 rioters were killed. War projects undertaken by the British and U.S. governments at Nassau and elsewhere during 1942 and later years caused a considerable labour shortage for a time, especially in forms of employment which could not compete with the high wages paid on government projects, but it was necessary in the latter part of 1943 for the colonial government to set up a special Out Islands department, designed to formulate work projects which would draw unemployed workers away from the capital. An arrangement was made in May 1943 for the transportation of up to 6,000 Bahama labourers to Florida to fill labour demands there. The colonial government in 1944 undertook a road building program for islands other than New Providence, partly with the design of relieving unemployment. The policy of temporarily transporting workers to the U.S. was only partially successful; by March 1944 only some 3,000 had migrated to the U.S. for agricultural labour, although 2,000 additional workers were then being

Outbreak of the war in Sept. 1939 was met in the Bahamas by legislative action putting the colony on a war footing, imposing a censorship, and appointing a food control committee to regulate prices and distribution of food. A popular subscription in 1940 raised more than $f_{20,000}$ for the purchase of aircraft for the royal air force, and during the same year the colonial government loaned to the British government the colony's treasury surplus of £250,000 on an interest-free basis for the duration of the war. The Bahamas in 1941 made extensive gifts of metals, money and foodstuffs to the empire cause and a further. interest-free loan of £100,000. Wartime financial conditions remained fairly satisfactory in 1943, although the war continued seriously to affect the Bahamas. Price control was effectively established in Dec. 1942; rationing of essential foodstuffs became necessary the following July.

Consummation of the Roosevelt-Churchill destroyernaval base agreement in 1940 involved the Bahamas as the site of two such bases. Mayaguana and Great Exuma islands were later agreed on as the specific sites, and initial work was undertaken in 1941. The U.S. formally took over the naval and air bases in September of that year, although construction had not yet been completed. Tempo of the work increased in 1942-43 and was continued actively until construction ceased in Nov. 1943; this work between May 1942 and Nov. 1943 resulted in an expenditure of £1,113,059. Speculation existed in the latter part of 1945 about the possibility of commercial use of wartime aviation installations.

Transportation and other economic factors were seriously affected by the war. The colonial government as early as 1939 completed a modern dial-telephone system for the city of Nassau at a cost of almost £70,000. The islands' main transportation links to the U.S. had been by means of tri-weekly air flights and services furnished by five steamship lines. Wartime exigencies brought quick disruption of the latter and the government was compelled, in Nov. 1939, to subsidize a U.S. line to maintain service through the winter. Maintenance of regularly scheduled shipping connections with the U.S. and other places became increasingly difficult in 1940 and 1941. With the conclusion of the war in 1945, transportation services appeared to be headed for a considerable expansion; six air lines were in that year considering the inclusion of Nassau in their itineraries. In the same year domestic transportation was improved by the completion of a 71-mi. road from Gregory Town to Bannerman Town on the island of Eleuthera.

Appointment of the duke of Windsor in 1940 as governor and commander-in-chief aroused considerable outside interest in the archipelago. The duke took an active part in Bahamian affairs until his resignation as governor on March 15, 1945 (effective July 28, 1945). He followed his resignation with the presentation to the chamber of commerce on March 29 of a development program for the islands and with a farewell address to the assembly on

April 4. A sensational development in Bahamian history occurred in July 1943 in the murder of Sir Harry Oakes, richest resident of the islands. His son-in-law, Alfred de Marigny, was accused of the crime but won acquittal in Dec. 1943 after a spectacular trial; the murderer was not discovered.

Considerable modification of production patterns and consumer habits was caused by the war at various stages. Since many goods, including foodstuffs, had been normally imported, the early disruption of shipping services quickly resulted in a shortage of consumer goods and in a rising cost of living. A partial remedy for the economic dislocation was found in the considerable sums remitted to the islands by agricultural and other workers who migrated to the U.S. during World War II; these remittances continued in fairly large volume through 1945. Inflation continued, however, and hence little improvement in living conditions resulted as a consequence of wartime prosperity. Merchants were the chief beneficiaries of the changed economic situation. The cost of living by 1945 was 125% above that for 1939.

Sponges in earlier years constituted a major export, but because of the prevalence of disease in 1938-39, all sponging grounds were closed by the government during 1941 and 1942. The industry remained practically suspended in 1943 and 1944 but by 1945 it showed signs of recovering. Sisal development in the Out Islands was greatly stimulated in 1942 by an agreement on the part of the U.S. to buy all the output as a partial substitute for blocked Philippine imports. In the same year a ten-year contract for the export of Bahamian spices (chili peppers, dill, fennel, ginger, paprika, pimientos, sesame seed, thyme and turmeric) to the U.S. was also consummated. The colonial government in 1943 took steps to promote seafood exports and straw and shellwork as a partial offset to the disrupted sponge industry. The government in 1944 imported 120,ooo mulberry cuttings from Venezuela in the hope of establishing a silk industry; only 40,000 of the cuttings survived; these were sold below cost by the British Caribbean Silk company, which also supplied the necessary silkworm eggs. Various oil companies sent representatives to the Bahamas in the early part of 1945 to investigate prospects for production, although no drilling was then undertaken. It was announced in mid-1946 by a Bahamian subsidiary of the Standard Oil Company of New Jersey that radar would be employed to hunt for oil underneath the ocean floor off the Bahamas.

Problems of political reformation arose at times during

the decade. The house of assembly on July 4, 1944, rejected a move for the secret ballot and after disapproval by the legislative council the unusual step of appeal to the secretary of state for the colonies was taken six days later. The house of assembly on July 3, 1945, asked for a greater degree of responsible government. On July 23, 1946, it extended the secret ballot, previously provided for New Providence, to the Out Islands. Considerable discussion took place in the latter stages of the war about the possibility of inter-colonial federation among the British units in the Caribbean, but the house of assembly on July 3, 1945, unanimously rejected a proposal of the British government that the various West Indian colonies should give consideration to the possibility of federation. Nevertheless, commercial and quasipolitical relations among the different British Caribbean colonies were strengthened. (See also West Indies, British.)

Balbo, Italo

Balbo (1896-1940), Italian statesman and aviator, was born in Ferrara, Italy, June 6, 1896. When Italy entered World War I in 1915 he enlisted in an Alpine corps and was decorated three times for gallantry. One of the early supporters of fascism, he was appointed undersecretary for air in Mussolini's cabinet in 1926 and in 1929 was named air minister. In 1933 he commanded 24 hydroplanes which flew from Rome to the Century of Progress exposition in Chicago and return. The flight made him so popular in Italy that he was mentioned as a possible successor to Mussolini. He was then appointed air marshal and governor general of Libya. He was killed June 28, 1940, according to an Italian communiqué, in an air battle over Tobruk, Libya, while fighting British planes. There were rumours, however, that his death had been planned and carried out by fellow-countrymen acting on orders from Mussolini.

Baldwin of Bewdley

Earl Baldwin of Bewdley (Stanley Baldwin, Viscount Corvedale) (1867—), British statesman, was born Aug. 3, 1867, at Stourport, Worcestershire, the son of an iron-master and M.P. He was educated at Harrow and Cambridge university, graduating from the latter institution in 1888. Elected to parliament in 1908 on the Conservative ticket, he became parliamentary private secretary to Bonar Law, then chancellor of the exchequer (1916). He was president of the Board of Trade in 1921 and was appointed chancellor of the exchequer in Law's cabinet in 1922. After Law's resignation because of ill health, Baldwin was named prime minister and leader of the party, May 20, 1923.

While the Conservatives were returned to power, a Liberal-Labour coalition voted "no confidence" in the new

government; as a result Baldwin resigned Jan. 22, 1924. The ensuing Labour government was short-lived and after the Conservative victory in the elections of Oct. 1924, Baldwin became prime minister again, Nov. 6, 1924. His gravest problem during his second tenure was the general strike of 1926.

In the general elections of May 1929, the Conservatives were swept from power and Baldwin resigned June 4, 1929. Caught in the great depression that started in that fateful year, Ramsay MacDonald subsequently formed a government of national unity, naming Baldwin to the post of lord president of the council (1931). After Mac-Donald's resignation, Baldwin took the helm for the third time, June 7, 1935. A year later, Baldwin, disturbed by the request of King Edward VIII that he be permitted to wed a U.S. divorcee, Mrs. Wallis Warfield Simpson, informed the king that this marriage would not receive the approbation of the people. Edward decided to forego the crown, marry Mrs. Simpson and leave Britain. After the coronation of the new king, George VI, Baldwin resigned May 28, 1937 and retired from public life. He was created 1st Earl Baldwin of Bewdley in 1937.

Baltimore

The seventh largest U.S. city, Baltimore, Md., had a population of 859,100 by the federal census of 1940; by the end of World War II this figure had increased to an estimated 930,000, excluding military personnel. Area, 78.58 sq.mi., plus 13.35 sq.mi. of water.

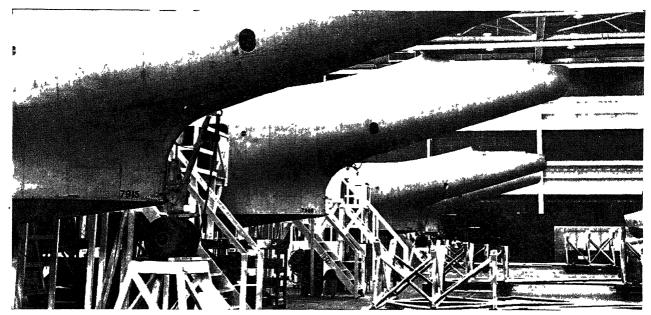

The white population in 1940 was 692,533; non-white, 166,567.

In 1937, Pan American Airways chose the Baltimore municipal airport as the base for its regular Bermuda service in conjunction with Imperial Airways and regular flights began Nov. 14. The first year of the decade 1937–46 also saw the first appointment of a Negro to the police force, the adoption of voting machines for all elections, the continuing substitution of busses for trolley cars and the razing of hundreds of buildings in the older parts of the city to make space for the parking of automobiles.

In 1939, Mayor Howard W. Jackson and comptroller R. Walter Graham were re-elected to office; Richard C. O'Connell was elected president of the City Council. A system of permanent registration of city voters was inaugurated.

A loan of \$5,000,000 for the sewerage system was approved by referendum in Nov. 1940. The first low-cost housing project was completed and opened for Negroes. Seven such projects were approved, estimated cost \$20,760,000. Three were for white families and four for Negroes.

The new municipal airport, opened Nov. 16, 1941, compared favourably with modern U.S. airports with its new-

Aircraft plant at Baltimore, Md., producing Martin PBM-3 mariner patrol bombers for the U.S. navy during World War II. This picture shows tail sections lined up in the plant's assembly room

type control towers and its airport and seaplane base facilities. Defense road construction called for an outlay of more than \$13,500,000. During 1941, Edmondson avenue was extended to the city line by a dual highway, and a cutoff was being built from the Philadelphia road to the Glenn L. Martin aviation plant.

Because of a decrease in city expenses of \$16,481 from tax levy funds, plus a decrease in the debt service and an increase of some \$94,000,000 in the taxable basis, a reduction of 20 cents per \$100 was possible in the tax rate for 1942.

War industries and steel plants accelerated operations to the fullest extent of available materials and workers after U.S. entry into World War II. Shipbuilding and aircraft plants maintained or exceeded schedules. Sixteen new industries and expansions in 90 plants were announced in the first twelve months after Pearl Harbor, and the boom continued throughout the remainder of the war. In addition to being an important shipbuilding, steel and aircraft manufacturing area, Baltimore became a major production centre of high-octane gasoline with the erection of a \$14,000 000 catalytic cracker at the Standard Oil Co. of N.J. refining plants in 1943. In 1944, the world's largest plant for the production of magnesium extruded shapes was completed.

Theodore R. McKeldin, Republican, was elected mayor May 4, 1943, and took office May 18, succeeding Jackson. His vote, 77,567, constituted a majority of 20,275 over Jackson, who was running for a 5th term. McKeldin, the first Republican mayor elected after 1927, received the largest majority ever given a Republican. Howard E. Crook, Democrat, was elected city comptroller. The council president, Thomas E. Conlon, Democrat, died in Oct., 1943, and the vacancy was filled by C. Markland Kelly. Democrats kept a solid membership in the city council.

For three successive years—1942-44 inclusive—business activity reached all-time peaks. Electric power output, department store sales and bank deposits all attained new high levels. The resources of Baltimore banks doubled during the war period. Shortly after V-E day in 1945, they aggregated \$1,659,700,000, representing about 75% of the bank resources of all Maryland.

The end of World War II brought a lessening of ship-building and ship-repair work. By 1946, reconversion was practically completed in most industries, the largest single reconversion project being that of the Chevrolet-Baltimore division of the General Motors corporation. Production continued vigorously in these lines, among others: metals and metal goods, distilled liquors, plastics and electrical goods (including radios). While many workers received unemployment compensation, few who desired available work were unable to obtain it. (C. B. S.; E. Gn.; X.)

Bank for International Settlements

The prewar tension in Europe and World War II itself, as well as the postwar period, had their repercussions on the operations and management of the Bank for International Settlements. In the autumn of 1939 the governments in London and Paris, after careful consideration, came to the conclusion that the bank, to which an American, Thomas H. McKittrick, had just been appointed president, should not be discontinued during the war. The bank laid down for itself, at the same time, certain principles to which it strictly adhered; among them was the principle of scrupulous neutrality by which it limited itself to operations which would "stand as above reproach both from the point of view of belligerents and neutrals." As a result, the volume of the bank's business was considerably reduced but, even so, it was able to render services to many central banks, and especially those of countries which were occupied in the course of hostilities; for instance, it held gold and deposits for the account of such banks all through the war years.

The total of the bank's balance sheet, which at the end of March 1937 stood at 619,000,000 Swiss gold francs, was reduced to 451,000,000 Swiss gold francs by the end of March 1946. Up to the very end of hostilities the bank was able to obtain full transfer of interest earned on its investments in different markets. In addition, substantial reimbursements were obtained on credits granted before

the war in various countries on the continent of Europe. The net assets of the bank on the U.S., British and Swiss markets, held in gold, dollars or Swiss francs, rose on the aggregate by more than 117,000,000 Swiss gold francs (the equivalent of nearly \$40,000,000) during the war period between Aug. 31, 1939, and March 31, 1945. In its 16th annual report, the bank stressed the fact that no attempt had been made from any quarter to influence, in an incorrect manner, the management of the bank in carrying out its affairs or to induce it to depart from the principles which had been adopted at the beginning of the war.

While the war lasted, the bank was able to cover its costs of administration and pay a dividend, which, however, gradually was reduced from 6% at the beginning of the war to the equivalent of 4.72% in 1943 and 4% in , 1944. In 1945 no dividend was paid; it was thought necessary to make the maximum possible provision for future contingencies. For the financial year 1945-46, a deficit was incurred, caused partly by transfer difficulties at the end of the war and partly by the maintenance, for the time being, of a high proportion of assets in gold. The bank's remaining investments in Germany were all made exclusively in the period 1930-31 and were the result of explicit obligations laid upon the bank by the Hague agreements in the interest of the countries which were the reparation creditors of Germany, the bank having, under those agreements, certain rights and privileges.

Throughout the war the bank continued to make available information regarding monetary regulations, clearing arrangements, etc. and, in particular, to publish its annual reports, containing extensive reviews of the economic and monetary situation all over the world, but particularly in Europe. These annual reports were, in fact, much enlarged, extending to more than 300 pages, in response to a universal demand for information at a time when most other reports of a general character were no longer issued. Covering the postwar period, the 15th annual report was published by the end of 1945 and the 16th report in July 1946. (See also International Bank for Reconstruction and Development.)

Bankhead, William Brockman

Bankhead (1874-1940), U.S. statesman, was born in Moscow, Ala., April 12, 1874, the son of John Hollis Bankhead, who later was elected to the United States senate. He was graduated from the University of Alabama in 1893 and from Georgetown university law school in 1895. After two years in New York city he went to Huntsville, Ala., where he began the practice of law. He served one term in the Alabama legislature and in 1916 was elected to the national house of representatives, and was re-elected to 11 successive congresses thereafter. He was named chairman of the house rules committee in 1934 and floor leader in 1935, and in 1936 he was unanimously elected speaker to succeed Joseph W. Byrns, who had died in office. He was the keynote speaker at the Democratic national convention in Chicago in 1940 and was an active candidate for nomination for vicepresident but was defeated in the convention. He died Sept. 15, 1940, in Washington, D.C.

Banking

At the end of 1946 there were more than five times as many banking units in the United States as there were in all the rest of the world. This was true despite the fact that there had been a steady decline in the number of banks from the high point of 31,811 in 1921. The number at the end of 1946 was 14,838. The number of banks in all other countries was only 2,843.

Likewise, there were more dollars of resources in U.S. banks than in any other country. The high point in total resources was reached in 1946, when the bank resources for all 48 states amounted to more than \$173,000,000,000. Of the total, nearly \$161,000,000,000 were deposits.

To indicate the tremendous growth during the decade, it should be noted that in 1936, the total resources were only about \$70,500,000,000. That year, deposits totalled only \$61,500,000,000.

By comparison, the total assets of 11 London banks (known as the "clearing house banks") were \$28,034,000,000 in 1946. The 11 largest banks of the U.S. had assets of \$33,633,901,000 that same year. The total assets of all 10 Canadian banks were a little less than \$9,000,000,000. Two of the largest banks in the United States together had total resources greater than the latter amount.

All of these figures represented tremendous growth for the decade 1937–46. The growth is shown by the following comparison of total resources of banks in the three countries for the years 1936 and 1946.

Table I.—Total Resources of U.S., London and 10 Canadian Banks, 1936 and 1946

United States Banks
1936 . . . \$70,425,027,000 (15,738 banks)
1946 . . . \$173,263,977,000 (21 banks)
1946 . . . \$173,263,977,000 (14,861 banks)

U Canadian Banks, 1936 and 1946

10 Canadian Banks

10 Canadian Banks

10 Canadian Banks

23,140,000,000

(18 banks)

The largest bank in the United States was the Bank of America, National Trust and Savings association of San Francisco, Calif., with total resources on June 29, 1946, of \$5,500,000,000. The second bank in point of size on that date was the Chase National bank of New York city; it had more than \$5,000,000,000 in total resources.

The National City bank of New York had more than \$5,000,000,000; the Guaranty Trust company of New York had more than \$3,000,000,000; the Manufacturers Trust company of New York had more than \$2,000,000,000. The Continental Illinois National Bank and Trust company of Chicago had more than \$2,000,000,000, as did the First National bank of Chicago.

The Bank of England had total resources of \$1,881,000,000, Oct. 30, 1946. The largest London bank, Midland bank, had resources of less than \$2,000,000,000. The largest bank in Canada, the Royal Bank of Canada, had total resources on the same date of more than \$2,000,000,000. There were 3 other banks in Canada with more than \$1,000,000,000 in total resources: the Bank of Canada, the Canadian Bank of Commerce and the Bank of Montreal.

Four large French banks had total resources of \$1,970,337,600.

There was a time when the largest bank of the world was in England, but the United States in 1946 had eight banks, each larger than any London bank in total resources. There were 16 U.S. banks with more than \$1,000,000,000 in total resources each, 3 with more than \$5,000,000,000,4 with more than \$3,000,000,000 and 7 with more than \$2,000,000,000. This tremendous growth was not entirely because of World War II; between 1936 and 1940, for example, the total resources of banks in the United States increased more than \$10,000,000,000. Between 1940 and 1946, the increase was more than \$96,000,000,000.

Small Changes in Capital.—While the capital structure of U.S. banks increased as deposits increased, the actual amount of capital in dollars was not much more in 1946 than it was in 1923. However, there were more than twice as many banks in 1923, which indicated that banks had more than twice as much capital per bank in 1946.

Capital funds greatly increased as deposits increased. For example, when deposits were only \$47,000,000,000 in 1923, capital funds were nearly \$7,000,000,000. In 1936 deposits had increased to \$58,000,000,000 and total capital funds increased to more than \$8,000,000,000. In 1946 when deposits were at the high point of \$161,000,000,000, capital funds were at the all-time high of \$11,500,000,000.

The plan for protecting depositors in United States banks was to increase surplus and reserve rather than to increase capital, for capital appears to remain about the same in total dollars no matter where the deposit total goes. There had never been a time when the capital of all U.S. banks was so much as \$4,000,000,000. Likewise, when deposits got down to \$42,000,000,000 in 1933, there was still more than \$3,000,000,000 in capital.

Surplus is largely built up from bank earnings, and most banks pride themselves on having surplus equal to or greater than capital. In 1946 capital stood at a little more than \$3,000,000,000, whereas surplus was nearly \$5,500,000,000. In addition to that, there was a reserve fund including undivided profits of \$2,702,818,000.

It should be understood that undivided profits are earnings from which dividends are paid to stockholders. However, the board of directors of a bank sets aside a part of these undivided profits for reserves. In some cases, there are several different kinds of reserves with titles such as the following: reserves for contingencies, reserves for losses on loans, reserves for losses on securities. If and when losses do occur, they are paid out of these reserve funds. Because of this type of capital structure, individual banks are able to withstand tremendous losses if they should occur. As a matter of fact, losses were very small in banks of the United States during the decade 1937-46, actually totalling less than 1% of invested funds. The record of most banks was only a very small percentage of 1%. Lending and investment policies of U.S. banks had been so highly developed that losses seldom occurred.

Multiplication of Earning Assets.—Inasmuch as a bank's expenses and profits must be earned largely by investing the funds on deposit, it is important to know how these funds are invested and at what rate. As already noted, deposits greatly increased during the decade. Also during those ten years, investments in government bonds and in loans and discounts were increased by a large amount. For example, investments of banks in the United States in government securities rose from \$17,000,000,000 to \$96,-500,000,000. Investments in loans and discounts increased about \$11,000,000,000, from about \$21,000,000,000 to \$32,-000,000,000. The one classification which showed a decline was "other securities," including bonds issued by railroads, municipalities, public utility companies and commercial firms. Total investments in "other securities" decreased from about \$11,000,000,000 in 1936 to \$9,000,000,000 in 1946.

The total invested funds of banks of the United States in 1946 were nearly three times as much as in either 1936 or 1923. In 1923 the total of invested funds was about \$46,000,000,000. In 1936 they had increased to nearly \$49,000,000,000. In 1946 they stood at \$137,651,811,000.

Decline of Interest Rates.—The decade was an era of declining interest rates; while deposits and invested funds increased, the rate of earnings on these funds declined.

As an indication of this, the rates on government bonds made the following changes: in 1943 government bonds maturing in 7-9 years and taxable yielded a rate of 1.96%; in 1944, 1.94%; in 1945, 1.60%. There was a little gain in 1946, the rate being 1.62%.

On bonds maturing in 15 years or more, and partially tax exempt, the rates were as follows: in 1943, 1.98%; 1944, 1.92%; 1945, 1.66%. There were no such bonds available in 1946. Fifteen-year and more maturity taxable bonds had a rate in 1943 of 2.47%; in 1944, 2.48%; 1945, 2.37%; 1946, 2.27%.

Government borrowing undoubtedly fixed rates which forced bank rates down. In 1943 the rate on commercial loans in 19 cities averaged 2.72%. In 1944 the rate was 2.39%. In 1945 the average was 2.09%. In 1946 it was 2.32%.

It must be emphasized that these were rates in the larger banks in the larger cities and for large well-secured loans. Rates in smaller banks were seldom that low. Some bankers in smaller places were still getting 6% as in previous years for most local loans; others were lending at 5% and a few at 4½% or 4%.

The income from municipal bonds issued by states, counties and cities also showed a decline in rate during the ten years. In 1943 the rate averaged 2.06%; in 1944, 1.86%; in 1945, 1.67%. There was a little improvement in 1946, with the rate averaging 1.87%.

Railroad bonds had an average yield of 3.64% in 1943, 3.39% in 1944, 3.06% in 1945 and 3.07% in 1946. Public utility bonds showed a decline during this period from 2.99% in 1943 to 2.77% in 1946. Railroad bonds also declined from 3.64% in 1943 to 3.07% in 1946.

Thus, the income of U.S. banks was not at so high a rate. It was fortunate, therefore, that deposits were at a high level during this period so that the banks in general had adequate earnings for increasing surplus and reserves and for paying good dividends.

Rates in other countries also declined during the period according to the following schedule of discount rates of central banks:

England: 1939, 4%; 1946, 2%.
France: 1936, 3%; 1946, 13½%.
Germany: 1936, 4%; 1946, 3½%.
Belgium: 1938, 4%; 1946, 2%.
Netherlands: 1936, 3%; 1946, 2½%.
Switzerland: 1936, 2%; 1946, 1½%.

It would appear reasonable to characterize the decade 1937-46 as one in which banking in the United States was becoming stabilized. The number of banks was being adjusted to commercial needs; the surplus and undivided profits and reserves of banks were being increased to correspond with increased deposits. Earning assets were increasing rapidly, although rates were going down.

Deposit Insurance.—Federal Deposit insurance originated in the United States in 1933. The federal law required that all national banks and all members of the federal reserve system join the Federal Deposit Insurance corporation (FDIC). Congress provided that the federal reserve system must advance funds in order to put FDIC on a solid footing at once, and the corporation assessed the insured members on the basis of their deposits. During the decade 1937–46, the funds of the FDIC, representing the insurance fees paid by member banks, increased to such an extent that officers of the corporation urged in 1946 that at least a part of the original capital supplied by the federal reserve system be returned. In other words, the banks themselves had built up a sufficient insurance

fund to protect all deposits in all insured banks up to \$5,000 against any loss from the closing of any insured bank.

There were very few bank closings during the decade, not only because of the protection offered by the fund, but also because of additional examinations made by the FDIC. Where these examinations disclosed a weak condition (which occurred in very few cases) recommendations were often made for merging the weak institution with some stronger one.

As another result of the satisfactory experience with deposit insurance, it was suggested that the insurance apply to deposits up to \$10,000 instead of \$5,000.

State banks which were not members of the federal reserve system were privileged to join the FDIC as well as members, and many of them did so during the decade. In 1938, for example, there were 997 state banks which were not insured, whereas at the end of 1946, there were only 696. These were all small institutions with state charters.

Modification of Investment Policies.—Investment policies of United States banks underwent changes during the decade in such a way as to reduce greatly the possibility of losses on investments made by banks. Much more caution was exercised in lending money on speculative real estate transactions such as the financing of subdivisions and the like. Also, more caution was exercised in the selection of bonds issued by foreign countries.

By the end of 1946, United States banks could supply funds for any industrial expansion; there was no limit to which loans could be made available to borrowers when industry was in legitimate need of funds. This was because of the correspondent system of banking and the federal reserve system. The correspondent system, with its interbank relations, had made it possible for one bank to borrow quickly from one or more other banks.

Term Loans.—Even large sums which were formerly obtained by industries only by issuing bonds could now be obtained by direct bank loans. If the sum required was larger than the legal limit of one bank, several banks together might set up a term loan commitment to be drawn against by the industry over a specified period in any amount up to the total and at any time.

This was one of the more important developments in U.S. banking during the decade. More term loan commitments were issued than ever before. As an example, a large corporation might have in mind expansions requiring the use of \$75,000,000. Not all of this would be needed at one time or for the total period over which the money might be used. The treasurer of the corporation, therefore, would go to one of its banks of deposit, or to a federal reserve bank, explain the situation, and supply all of the necessary information. This bank then would contact other banks (its correspondents) and a pool or syndicate would be set up whereby each bank agreed to supply a certain part of the credit and at certain rates.

The corporation would then be given a "commitment"—an authority to draw against the fund set up, as needed. For this commitment, the corporation would pay a very small fee which, in the end, was much less than it would cost the company to float a bond issue. With a commitment, any amount might be used at any time and be repaid as funds became available.

This arrangement was often referred to as a "revolving credit." If the commitment was for \$75,000,000, \$20,000,000 might be used in one year and returned the next.

Almost immediately, \$30,000,000 might be withdrawn and used; but in the meantime, only the commitment fee was paid on the total amount, and the interest rate agreed upon was paid only on the amount of money actually in use, and for only the period of time used.

Here again, the correspondent system showed its worth. If such a pool was for a large amount, usually it was larger banks that made up the pool. If it were for a small amount, a city correspondent originating the credit might include some of its country correspondents in the pool. Small banks would, therefore, benefit by this type of investment.

Participation Loans.—Another important development of the decade 1937–46 was the increased lending of federal reserve or correspondent bank funds in co-operation with other banks. Each unit bank was limited by law as to the total amount it could lend to any one borrower. If a bank in a country town had a demand for a big loan which was larger than it could legally make from its own funds, it could, in co-operation either with a correspondent or with the federal reserve bank, make the entire loan by the simple plan of sharing the loan with either the correspondent or the federal reserve bank, the larger bank taking the amount of loan above the legal limit of the smaller bank.

The extreme flexibility of credit, however, was best illustrated by the fact that, when a federal reserve bank loaned money, it did not lend its deposits which were the funds of member banks, but it actually created deposits by issuing federal reserve currency. This was a provision of the law which provided unusual benefits to U.S. business during the decade; it illustrated the fact that there was no limit to the amount of credit available to industry.

Individual Credit.—By the end of the decade, most U.S. banks had adopted the practice of lending to any person with an income, funds for the purchase of such commodities as automobiles, electric refrigerators, furniture, etc., to be repaid in convenient instalments either weekly or monthly. Prior to the decade, the majority of such loans had been made by small loan companies, industrial loan companies or credit unions. In 1936 commercial banks had outstanding loans of this type amounting to \$161,000,000, while loan companies at the same time had outstanding loans of \$301,000,000. The position was reversed, however, in 1946. In October of the latter year, commercial banks had a total outstanding of \$864,000,000 compared with only \$556,000,000 outstanding in small loan companies. In many cases, banks offered lower rates on these loans and greater convenience.

Checking Facilities.—Still another interesting development of the decade was the offering of bank-checking service to individuals who could not maintain a fairly large balance. While there were a number of different types of no-minimum-balance checking accounts, it was quite common for a bank to charge ten cents for each check written and allow the customer to keep any balance he desired. Thus, a person with a balance of only \$100 could have a bank account that saved him considerable time and expense because of his ability to write checks and mail them to his creditors.

A system of payment for banking service was also developed by which a customer paid for only that amount of service not covered by the income the bank derived from his balance. This type of service was commonly called "service charge service" and was used by customers with larger balances, and especially by those who must write many checks each month.

Banks devised various schedules by which they gave credit for the balance and made charges for the service used. Some larger accounts maintained balances sufficient to cover all the charges and had no service charge at all. Others had so many transactions that the service charge was necessary, but even in those cases, the total amount of the charge was comparatively small, and it represented an economy in the use of banking services over other methods of financial transactions.

New Types of Collateral.—A lending service known as "accounts receivable loans" had considerable growth during the decade 1937-46. A customer needing operating funds pledged his accounts receivable by providing the bank with a list. When the accounts were paid, the funds, being earmarked for the bank, were turned over to the bank to liquidate the loan. Some firms found it greatly to their advantage to use this new type of loan service. Another type, the "field warehouse loan," developed to a remarkable extent during the decade. "Field warehouse companies" with financial responsibility would take charge of a customer's raw products or finished goods in the customer's own warehouse. The company would actually rent the space in which the goods were stored, would place a bonded custodian in charge and issue warehouse receipts representing the quantity and quality of the goods in storage.

These receipts were accepted by banks as collateral for loans. The field warehouse company had custody of the goods and was responsible for keeping them intact until the bank issued a release for a part or all of them. If, for example, a borrower had need to withdraw a carload of goods thus stored for processing or shipment, he would make a satisfactory payment of part of his loan to the bank, and the bank would issue a release on the quantity of goods to be shipped. This release would then be turned over to the field warehouse company, and the goods would be loaded.

Reduction of Exchange Charging.—Among the many improvements in bank-operating techniques during the decade, one having to do with the charging of exchange on checks was notable. A number of U.S. banks had long made a charge against a check drawn on the bank by one of its customers; but this charge, instead of being made to the customer, was made to the payee.

If a local lumber dealer bought a carload of lumber and wrote a check for \$3,000 against his local bank payable to a wholesale lumber firm in a distant city, the lumber firm would not receive the full amount of the check because an amount was deducted by the bank on which the check was drawn (known as "exchange"). This amount had not been uniform (it might be as much as \$30) and, therefore, the system resulted in considerable confusion.

There was a marked tendency during the decade to eliminate this charge. A bank that paid all of its checks in full became known as a "par bank." The number of "par banks" increased to such an extent that only 2,095 banks were on the nonpar list as of Oct. 31, 1946. All national banks and all federal reserve member banks paid their checks at par. On the date mentioned, in addition to member banks, 5,057 nonmember banks were paying all of their checks at par.

Protest Charges.—A marked development during the decade in protest requirements was of great benefit to industry. The progress indicated that protest charges might be eliminated entirely except when the payee asked to have a check protested.

The law, as it stood at the end of the decade, required that a bank protest any foreign bill (payable at a bank in

a state other than the state in which the bill was drawn) dishonoured for any reason. When this was done, the notary public making the protest charged a fee, usually not uniform. Furthermore, these fees were assessed for a service which had been of no benefit to the payee. Therefore, not only bank executives but also members of the American Bar association developed a movement to bring about a change of the law in each state to require banks to protest dishonoured items only when the payee asked that such protest be made.

Britain's "Big Five."—The nationalization of the Bank of England was the high point in British banking during the decade 1937–46. (See BANK OF ENGLAND.)

The five largest British banks in order of size with their "deposits and other accounts" at the end of 1945 were as follows:

Bank of England	\$1,680,387,805
Midland bank	
Barclay's bank	917,775,560
Lloyd's bank	
Westminster bank	598,934,131

These 5 banks alone had 10,280 branches, many in other countries. There were eight banks with head offices in Scotland, and nine in Ireland.

Resources in British banks more than doubled during the 10-yr. period; assets of 21 British banks in 1936 were \$12,871,630,570, and the assets of 18 banks in 1945 were \$24,523,752,370.

The five largest privately owned banks continued to serve as London agents for banks in all countries. The Midland bank served banks in 46 countries, Barclay's in 61, Lloyd's in 73, Westminster in 52 and National Provincial in 94. British banking was emphatically international.

Branch Banking.—In all countries except the U.S., the branch-banking system continued to prevail. The 10 banks in Canada, for example, had 3,166 branches. When the branches of the United States banks were added to the head offices, there were 19,035 banking offices, but only about 1,000 United States banks had branches; all the others were single units. The 13,838 United States banks without branches were classified as "independent" institutions or "units."

Branch banking existed in 42 states and the District of Columbia in 1946, with the largest numbers in the following states: California (885), New York (753), Massachusetts, Michigan, North Carolina, Ohio, Washington and Wisconsin (each with more than 100). (J. Y. B.)

Mutual Savings Banks.—During the decade 1937-46 inclusive, international problems with their consequent impact upon national economy shaped the growth and activity of mutual savings banks. In the United States, three major developments dominated the operation of these institutions. The most spectacular was a 60% increase in deposits, most of which occurred in the 3 years

Table II.—Mutual Savings Banks of the United States

1945			3.57%	62.78%	6.33%	24.77%	.78%	1.77%

ending Dec. 31, 1945. Less dramatic, but of great importance, was the change in the character of savings bank assets, and the contribution the banks made to the U.S. defense and war effort by acting as agents for the issuance and redemption of United States savings and war bonds.

The spectacular increase in savings bank deposits, occasioned by a 50% expansion in national income from 1940 to 1945 and a lack of consumer goods available for purchase, was accompanied by a steadily declining average dividend rate. The huge quantity of funds seeking investment, the necessity of maintaining a low-interest rate policy on the part of the government in order to facilitate financing World War II, and the virtual suspension of private borrowing resulted in a continuous decline in the investment return of all lending institutions. The consequent reduced earnings restrained any increase in dividends to depositors and retarded the accumulation of surplus assets. Large holdings of government bonds and the provision of generous reserves for mortgage revaluation provided the protection formerly supplied by rapid surplus accumulations.

Character of Assets.—Responding to the needs of the country, U.S. savings banks subscribed heavily to the war bond drives for their own accounts. At the end of 1945, 62.7% of all assets of these institutions were invested in government securities as compared to less than 20% in 1936. This represented an increase in government bond holdings of more than \$8,000,000,000. This increase resulted from the investment not only of new funds but also the proceeds of liquidation of other types of assets.

Prior to the depression of the 1930s, mortgage loans were the major outlet for savings bank funds. These investments, because of their relatively high return, greatly helped to provide income sufficient to pay substantial dividends on deposits and were a major contribution to community development. The collapse of real estate values in the depression, followed by heavy foreclosures, necessitated a long period of readjustment in many mortgage investments. Borrowers were given every consideration, and adjustments of principal to prevent foreclosure whenever possible were part of a realistic approach to the problem taken by the savings banks. If foreclosure was unavoidable, the property acquired was rehabilitated and sold; terms of the resulting purchase money mortgage almost invariably called for amortization of the outstanding debt. Liquidation of the "other real estate" account of the savings banks made up of properties taken by foreclosure or voluntary assignment had been almost entirely accomplished by the end of 1945.

During the decade 1937-46 many mutual savings banks were active in making mortgage loans issued by the Federal Housing authority. In the war period, when ordinary building was curtailed, loans on homes built under the war housing provisions of the National Housing act provided the chief opportunity for mortgage investments. After the war's end, loans to veterans insured by the Vet-

erans' administration furnished an additional outlet.

In spite of aggressive effort, savings banks found it very difficult to make sound additions to their mortgage portfolios. In 1936 this type of investment had accounted for 43% of the banks' assets, but in 1945 the percentage had shrunk to 25. Halting of construction during the depression, enforced curtailment of private building during the war and the postwar bottlenecks in materials and labour were the major factors in the scarcity of suitable new mortgage investments.

In New York state, the total permissible percentage of assets invested in noninsured mortgage loans was reduced by statute from 70% to 65%, including real estate acquired through foreclosure. On the other hand, authority to make loans insured by the Federal Housing administration was extended beyond the limits of the state to include all adjoining states. Mortgage loans not subject to insurance, on properties in adjoining states, were legalized provided the underlying security was situated within 25 mi. of the principal place of business of the lending bank. In 1943 New York savings banks were given authority to lend up to 80% of appraised value on single family, owner-occupied residences constructed not more than 2 years prior to the making of the loan, provided such property was within 50 mi. of the lending bank.

In other states, similar liberalization of mortgage-lending legislation sought to provide adequate credit for the construction of low-cost homes. In Connecticut, New Jersey, Vermont and Washington the percentage limitation of loans to appraised value was raised to 80%, and in Massachusetts to 75%. Formerly, limits had been set at 70%.

Until the depression of the 1930s, railroad bond investments ranked second in importance to real estate loans in most savings bank investment accounts. At the end of 1931 they represented 13.98% of the combined assets of all savings banks in the United States. At the end of 1945 they had fallen to 2.69% of total assets through liquidation of impaired liens and a general flight from the railroad security field.

Sale of Government Bonds to the Public.—In addition to the heavy purchase of government securities for their own accounts, savings banks were instrumental in placing a large volume of savings, defense and war savings bonds in the hands of individual investors as shown below:

Table IV.—Savings, Defense and War Savings Bonds Sold By Mutual Savings Banks in the U.S.

May 1, 1941-April 30, 1942	\$420,143,000
May 1, 1942-April 30, 1943	489,762,000
